Date: July 06, 2026

Report Number: AR2026-0009

Report Name: Oilseeds and Products Update

Country: Argentina

Post: Buenos Aires

Report Category: Oilseeds and Products

Prepared By: Chase McGrath

Approved By: Chase McGrath

Report Highlights:

Post raises MY2025/26 soybean production forecast to 50 million metric tons (MMT) on higher than expected yields reported, while maintaining planted area at 16.5 million hectares (MHA). As of writing, the crop was 98 percent harvested, in line with last year's pace. With additional supplies available, Post also raises MY2025/26 soybean crush to 43.5 MMT, up 500,000 metric tons. Post maintains whole soybean export forecasts at 5.5 MMT. Post also raises MY2025/26 sunflower production to a record 7 MMT, up 500,000 metric tons from the annual report, reflecting larger than previously reported planted area and record nationwide yields estimated at 2.3 MT/HA. MY2025/26 marks Argentina's highest sunflower area, production, and yield on record, surpassing the previous record set just one year earlier. By contrast, Post lowers MY2025/26 peanut production to 1.1 MMT as wet and cold conditions delay the harvest, combined with earlier drought stress during key crop development stages in Córdoba, reduced yields.

SOYBEANS

Production

MY2026/27

Post maintains the previous forecast for Argentine soy production at 49 million metric tons (MMT) on 17.4 million hectares (MHA) planted area for marketing year 2026/2027 (MY2026/27) since Post's annual report in April.

Argentina produces two soybean crops each year, commonly referred to as first soy (soja primera) and second soy (soja de segunda). First soy is typically planted from late October through mid to late December and harvested from early April through the end of May. This crop represents the majority of total production with much higher yields.

Second soy is planted later, from late December into early January, immediately following the harvest of winter wheat, and is typically harvested from May through early July. It is commonly grown in a rotation with corn followed by winter wheat, then soybeans. Due to its later planting window and shorter growing season on fields that already produced a wheat crop, second soy generally yields significantly less than first soy. Approximately 70 percent of total soybean area is planted to first soy, with the remaining 30 percent allocated to second soy.

Despite the projected increase in area, yields are expected to decline slightly in MY2026/27 from the previous year, as many regions are currently experiencing historically high yields, particularly for second soybeans. Yields are expected to return to average levels under normal weather conditions. However, this outlook could shift if an El Niño pattern develops, which typically brings above-average precipitation to Argentina. Many in the industry expect a "super Niño" year which could boost yields higher.

Fertilizer prices will be a key factor in MY2026/27 and will likely shape final planted area. Fertilizer prices spiked by over \$200 per ton in Argentina in just one week after the operation in Iran sent global fertilizer prices rising. Fertilizer prices in Argentina have since come down to February levels. But if fertilizer rises again and remain high at planting, it could push more producers to favor soy over corn as soy has substantially less fertilizer requirements. As of writing, farmers are making their planting estimates and decisions based on current fertilizer prices but carefully watching prices.

MY2025/26

Post increases its soybean production forecast to 50 MMT in MY2025/26 on higher yields reported so far in the harvest. Post maintains the previous planted area estimate at 16.5 MHA.

The MY2025/26 soy crop was 98 percent harvested as of writing, on par with progress at this point in the season last year. The only remaining areas of second crop soy to be harvested remain mostly in northern La Pampa and western Buenos Aires provinces where significant moisture in the soil has delayed the ability to get into fields to harvest. Weather and soil conditions continue to prevent harvest in some fields in western Buenos Aires province, Corrientes, and northern Santa Fe province.

Post's increased production estimate is primarily driven by higher than expected yields, supported by favorable weather conditions during the final three months of the growing season. Post estimates the national average yield at 3.13 MT/HA, significantly above the five-year average, even when accounting for the drought-affected crop three seasons prior.

Yields are equally high in both first and second soy crops this year driving the overall yield increase for this year's crop thanks to abundant rainfall in most of the major growing areas as the ideal time in the growing window of late March and continuing throughout April. There are some reports of yields as high as 5 MT/HA in some of the most fertile production areas of the "zona nucleo."

In several growing areas outside the traditional highly productive "zona nucleo" record yields have been recorded for those areas included the north of La Pampa province and western Buenos Aires province.

Although late-season rains caused some harvest delays and complicated fieldwork, they did not result in significant quality or production losses. Instead, the additional moisture helped support above-average yields, offsetting the impact of reduced planted area and contributing to a strong MY2025/26 crop.

Source: Gentileza Dante Garciandia

Crush and Consumption

MY2025/26

Post increases crush to 43.5 MMT, up 500,000 MT from Post's last update, for MY2025/26 on increased available production. Domestic feed demand remains steady at 5 MMT with little fluctuation each year in Argentina's domestic demand.

Crush margins have come down from recent highs to around \$20 per ton. While these margins could depress crush in the next several months, Post maintains its previous crush estimate for the marketing year as crush is expected to recover later in the year in line with historical norms. Lower soy oil prices and rising soybean prices are expected to continue to push crush margins lower over the next several months.

Farmer selling has declined in recent weeks and to slightly below pace at this point in the season. Industry contacts estimate nearly one third of the MY2025/26 soybean crop has been sold to date though many of these sales were made without prices, indicating farmers expect prices to rise in the coming months.

Argentine soybean commercialization remains unusually slow this year, despite a larger crop forecast. According to the Rosario Board of Trade, only 22 percent of the soybean crop has been sold with a firm price, the lowest share since at least MY1994/95. Total soybean purchases by crushers and exporters reached 18.1 million tons, of which 10.4 million tons have a fixed price and 7.6 million tons remain unpriced. The slow pace of firm-price sales comes even as the crop is forecast up.

Producers have been reluctant to fix soybean prices due to a combination of market, financial, and logistical factors. Although soybean prices in dollar terms are 18 percent higher than a year earlier, the increase is only 8.5 percent in inflation-adjusted peso terms and remains below the historical average. Many producers have already met their near-term cash needs through sales of other crops such as corn, wheat, barley, and sunflowerseed, reducing their pressure to sell soybeans. In addition, earlier sales during the September 2025 temporary elimination of export taxes, harvest delays caused by repeated rains, and a transportation strike encouraged producers to hold soybeans rather than price them immediately. Argentine farmers use soybeans as their savings account and hedge against inflation and currency devaluation.

Argentina's soybean crush accelerated in recent months as the MY2025/26 harvest ramped up, supported by improved soybean availability, firmer soybean oil and meal values, and stronger producer selling in May. Official Argentine government data show soybean industrialization rising from 3.49 million metric tons in April to 4.19 million metric tons in May, bringing crush for the first two months of the local marketing year to roughly 7.68 million metric tons. May output included about 829,000 tons of soybean oil and 3.11 million tons of soybean pellets/meal. Argentina's MY2025/26 soybean crush forecast increase 43.5 MMT reflects a larger crop estimate and stronger domestic supplies, with higher crush expected to lift soybean meal and oil production and support soybean oil exports.

Trade

Post maintains the previous forecasts for whole soybean exports for both MY2025/26 and MY2026/27 since the last update two months ago. Post forecasts Argentina's soybean exports steady at 5.5 MMT both this year and next.

Imports will decrease slightly in MY2026/27 to 6.5 MMT, down 500,000 MT from the previous year with Paraguayan production forecast lower from a year prior and increased domestic crush in Paraguay resulting in less exportable supplies from Argentina's number one supplier. Small volumes will be imported from Brazil and Uruguay, and to a lesser extent Bolivia, to meet Argentina's crush demand.

Argentina Soybean Exports Top Markets

Source: *Post with data provided by Nabasa, a local shipping agent, as Argentine official trade data includes exports under the market “confidential” by which companies are able to obscure the final destination for shipments.*

On June 3, 2026, Argentina reduced export taxes on wheat and barley, effective immediately, and a gradual reduction of soybean, soy products, corn, sorghum, and sunflower export taxes beginning in January 2027 through December 2028. The announcement was published as Decree 423/2026 in the Official Bulletin. These reductions will be contingent on the economic situation.

The reduction in wheat and barley export taxes, from 7.5 percent to 5.5 percent, comes at a key moment, as the planting season begins. Farmers had been expected to marginally reduce their planted area due to rising production costs, particularly fertilizers, and low wheat prices that have not kept pace with the increased costs. The tax cut could incentivize some additional wheat and barley planting and limit the extent of the decreased planted area.

Product	December 2023	June 2026	December 2027	December 2028
Soybeans*	33%	24%	21%	15%
Soy Byproducts	31%	22.5%	19.5%	14%
Sunflower**	15%	4.5%	4.0%	3.0%

* Monthly gradual reductions beginning in January 2027

** Six-month reduction beginning in January 2027

Reducing export taxes on agricultural products has been one of President Milei's core objectives, as he regards them as deeply distortionary. However, the country's fragile fiscal situation has prevented the

government from eliminating them overnight. This announcement marks what is effectively the third round of cuts since Milei took office in December 2023. The table below shows the level of export tax per commodity at the time Milei took office, their current level, and projected taxes into 2027 and 2028:

The local agriculture industry welcomed the recently announced tax cuts and the phased reduction trajectory for soybeans, corn, sorghum and sunflower beginning January 2027. These new conditions will improve Argentine farmers' returns by directly increasing their income. Export taxes on agricultural products were first introduced in 1955 and have fluctuated significantly across successive governments. According to a report by the Bolsa de Cereales de Córdoba, between 2002 and 2024 farmers contributed approximately \$150 billion in export taxes through sales of soybeans, corn, and wheat alone, none of which was channeled back into the sector in the form of improved railways, roads, highways, ports, or production support.

The chart below details per month the descending trajectory through December 2028:

Cronograma Baja Dex												
	2027											
	1	2	3	4	5	6	7	8	9	10	11	12

Source: Ministry of Economy

On June 4 the Government of Argentina announced that a consortium led by a Belgian firm, Jan De Nul and local firm Servimagnus S.A. will receive a 25-year concession to dredge and maintain navigational aids along the Paraguay-Paraná waterway, Argentina’s primary export corridor. The government stated that the contract will reduce logistics costs by 13.5 percent through planned deepening of the river and the adoption of new navigation safety technologies. The Paraná-Paraguay waterway runs more than 1,500 kilometers into the Atlantic Ocean and handles nearly 80 percent of Argentina’s agricultural exports, mostly soymeal, soy and sunflower oils, soymeal, and others. The waterway is also crucial for exports from Paraguay, Brazil, Bolivia, and Uruguay. While the concession marks a return to private-sector management after state administration began in 2021, environmental groups have challenged the tender process and raised concerns that deepening the river could affect the Paraná River’s natural dynamics.

SUNFLOWER

Production

Post maintains the previous forecast of 6.8 MMT Argentine sunflower production for MY2026/27. Post also maintains the previous planted area and yield estimates of 3.3 million hectares planted with an overall nationwide yield of 2.06 metric tons per hectare (MT/HA).

The expected expansion in area is driven primarily by sustained favorable prices. Sunflower prices have remained attractive for three consecutive years, incentivizing both existing producers and new to incorporate the crop into their rotations. At the same time, relatively weaker corn and soybean prices improved sunflower's comparative profitability, particularly at times of planting decisions. Input costs will also play a critical role as sunflower's lower fertilizer requirements make it an increasingly attractive alternative to corn, especially in an environment of persistently high or volatile fertilizer prices.

MY2025/26

Post increases MY2025/26 sunflower production to 7 MMT, up 500,000 MT from Post's annual report due to record yields reported nationwide and increased planted area than previously reported. The nationwide average yield is estimated at a record 2.3 MT/HA.

MY2025/26 marks a record year for Argentine sunflower production, the highest year on record for area planted, production, and yield. Beating the previous record set the year prior.

These record were driven by favorable weather conditions from planting and all throughout the growing season. With sufficient moisture needed at key times in the growing cycle.

The expanded planting area this year was in part thanks to additional acreage planted in the northern growing area particularly in Chaco and Formosa provinces.

Crush and Consumption

Post maintains its previous sunflower crush forecast at 5.6 MMT in MY2026/27.

Sunflower seed crush is forecast up slightly to 5.4 MMT in MY2025/26, an increase of 100,000 since Post's annual report on increased production. More than 75 percent of Argentina's sunflower seed production is expected to once again be processed domestically and exported as value-added products though more whole sunflowerseed is forecast to be exported this year than ever. EU demand is driving these increased exports with difficulty sourcing from its traditional market of Ukraine.

While many crush facilities in Argentina are capable of processing multiple oilseeds, including sunflower, most operators have been reluctant to switch from soybeans due to the additional costs and processes required to crush other oilseeds in the same plant. However, this dynamic is beginning to shift as sunflower crush margins remain high. Post contacts expect these favorable margins to persist into the next marketing year, incentivizing greater utilization of existing capacity for sunflower processing.

Trade

Post maintains the previous forecast from two months ago for Argentina's sunflower exports at 900,000 MT in MY2026/27.

Post forecasts MY2025/26 whole sunflower seed exports up to 1.1 MMT from the last update, and up substantially from the previous year driven by demand from markets in Eastern Europe.

Sunflower seed exports are expected to increase significantly this year, reaching up to 10 percent of total production, compared to historically negligible levels of less than 1 percent. This growth is driven primarily by demand from European markets, including Bulgaria and Romania, which have faced higher costs and supply constraints sourcing from Ukraine. As a result, the share of Argentina's sunflower seed production processed domestically is projected to decline modestly, with more than 80 percent expected to be crushed, compared to typical levels exceeding 95 percent in most years. These elevated levels of whole seed exports are expected to persist into MY2026/27 unless the situation with Ukraine's supply is resolved.

PEANUTS

Production

Post maintains previous forecasts for peanut production in MY2026/27 at 1.52 MMT on 420,000 hectares planted. This represents a modest recovery in planted area as the sector returns to more typical levels following this year's contraction. Yields are expected to average slightly above trend at 3.6 MT/HA.

Post lowers Argentina's peanut production to 1.1 MMT in MY2025/26 due to continued wet and cold weather conditions affecting the harvest. In addition drought stress during key stages of the crop cycle during the summer months in the key production area in southern Cordoba province reduced ultimate yields of this year's crop.

In Córdoba, adverse weather conditions are delaying the progress of the harvest. In Cordoba province, the largest peanut producing province, only 60 percent of the crop has been harvested to date. Excessive water in fields and wet soils coupled with lower than normal temperatures are delaying the ability to dry and harvest the peanut crop. May fields have been dug up, but drying and the ability to complete the harvest remain delayed. Some producers in some regions of southern Cordoba province are already reporting a loss of half their crop. Forecasts indicate continued rain and cold in the coming two weeks, delaying the harvest even further.

Peanut area declined sharply in MY2025/26 following a surge the previous year, when strong prices at planting encouraged expanded area. However, prices fell significantly by harvest, reducing returns and discouraging producers. In addition, some first-time growers were discouraged by the experience of growing peanuts, as they require more complex management than competing crops.

Crush and Consumption

Crush remains flat at 250,000 MT in both MY2026/27 and MY2025/26 as most of Argentina's peanuts will continue to be blanched and exported, rather than crushed.

Trade

MY2025/26 exports are forecast at 850,000 MT, the same from Post's last report.

Post lowers exports from its previous update to 1.1 MMT in MY2025/26 reflecting weaker international demand, particularly from China. Despite this slight reduction, Argentina is expected to remain the world's top peanut exporter, even as it ranks as the sixth largest producer globally. The vast majority of Argentine peanut exports are shipped shelled and blanched, with in-shell exports comprising only a negligible share of total shipments. Nearly all of Argentina's peanut exports will be destined to the EU once again, where they are sought after for their high quality, flavor profile, and low aflatoxin rates.

RAPESEED

Post maintains the previous forecasts for rapeseed for both marketing years. Argentine rapeseed production is forecast at MY2025/26 40,000 MT decreasing to 33,000 MT in MY2026/27.
