Date: March 31, 2026

Report Number: IN2026-0012

Report Name: Oilseeds and Products Annual

Country: India

Post: New Delhi

Report Category: Oilseeds and Products

Prepared By: Shilpita Das, Agricultural Specialist

Approved By: Joanna Brown, Agricultural Attaché

Report Highlights:

India's oilseed sector is expected to continue to shift as rapeseed consolidates its position as the top oilseed for a second year, driven by sustained price advantages over soybeans. Farmers continue diversifying away from soybeans toward more profitable crops such as corn and pulses, reducing overall oilseed acreage. However, the drop in acreage will be offset by the continued adoption of high yielding oilseed varieties, thereby stabilizing production. Poultry and livestock producers are expected to accelerate their shift from traditional soybean meal to cost-effective alternatives as ethanol blending expands supplies of distiller's dried grains and de-oiled rice bran. Edible oil imports are also expected to shift: palm oil is expected to regain market share as prices stabilize, while soybean oil imports are expected to rise on lower prices, and sunflower oil imports will likely fall due to supply constraints and higher prices from key suppliers such as Ukraine.

Executive Summary

Oilseeds: India's oilseed sector is undergoing a shift, with rapeseed expected to remain the top oilseed for the second year due to sustained price advantages over soybeans. Total oilseed production for the 2026/27 marketing year (MY) is forecast at 41 million metric tons (MMT), a slight decrease as farmers shift from soybeans to more profitable crops like corn, wheat, and pulses. Rapeseed output is projected to rise by two percent, supported by strong market prices and adoption of high-yield varieties. Soybean production is anticipated to decline for a second year, down three percent, as prices remain below production costs and farmers in Madhya Pradesh and Maharashtra switch to corn, aided by government ethanol procurement programs. Peanut production is expected to grow three percent as farmers move from cotton to the groundnut, while cottonseed output is anticipated to fall one percent as producers seek higher-value alternatives. Total crushing activity is projected to remain flat at 34 MMT, well below India's 50 MMT installed capacity.

Oilseed Meals: Total oilseed meal production for MY 2026/27 is forecast at 20.1 MMT, slightly below the current year's 20.2 MMT. Poultry and livestock producers continue to shift to more cost-effective feed alternatives due to high soybean meal prices and changing feed preferences. Soybean meal consumption is expected to fall seven percent, while rapeseed meal and peanut meal output are expected to grow three percent compared to the current year. Although India is expected to crush a similar volume of oilseeds overall, the total oil meal production is expected to decline because of lower domestic soybean production – a crop that yields more meal per ton than other major oilseeds. Increased crushing of lower-meal oilseeds such as rapeseed and peanuts will not fully offset this reduction of soybean meal. In contrast, meal exports are set for strong growth, with soybean meal exports projected to increase 13 percent on sustained European demand for non-GMO Indian meal, and rapeseed meal exports are forecast to rise ten percent, with China expected to be the top importer following record purchases in late 2025.

Oilseed Oils: FAS New Delhi projects India's total domestic oil production at 9.5 MMT, a slight increase from the current year's 9.4 MMT. Although total oilseed output is expected to decline, overall oil production is still projected to rise because a reduction in soybeans and a shift to oilseeds with higher oil extraction rates such as coconut, rapeseed, and peanut. Rapeseed oil production is expected to rise by two percent, while soybean oil production is set to decline by two percent, reflecting greater availability of rapeseed than soybeans for crushing. India will continue to rely on imports for about two-thirds of its vegetable oil needs. Palm oil imports are forecast to grow by three percent from the current year's 15-year low of 7.1 MMT, as weaker benchmark prices in Indonesia improve competitiveness. Soybean oil imports are expected to rise by two percent, supported by surplus production in South America. In contrast, sunflower oil imports are projected to fall by about ten percent, as supply constraints from Ukraine are likely to shift demand toward more affordable alternatives.

OILSEEDS SECTION

India's oilseed industry cultivates six principal crops, with production concentrated in four major categories: cottonseed, peanuts (groundnuts), rapeseed (mustard) and soybeans. These four crops constitute the backbone of India's oilseed output across various agro-climatic zones. Two additional crops—coconut (copra) and sunflowerseed—occupy niche positions within specialized market segments in traditional growing regions.

In the 2026/27 marketing year, the sharp differences in economic returns among major oilseed crops—first seen in 2025/26—are expected to continue to reshape production patterns. Rapeseed is expected to remain profitable, with prices sufficient to cover input costs and ensure solid margins for growers. In contrast, soybeans are expected to remain less economically viable, as prevailing prices do not offset production expenses. For a second year, this has led farmers to move acreage from soybeans to more lucrative options such as corn, rice, vegetables, and wheat.

Aggregate oilseed production is projected at 41 MMT for MY 2026/27, representing a marginal decline from the current year's level due to a drop in soybean and cottonseed production (see Table 1). The relative overall oilseed stability, however, reflects continued adoption of high-yielding seed varieties, and stronger price incentives for rapeseed and peanuts that encourage productivity-enhancing investments. Consequently, FAS New Delhi anticipates average yield will improve to 1.04 MT/Ha, partially compensating for reduced cultivated area and stabilizing the overall oilseed sector (see Table 1 and Figure 1).

OFFICIAL DATA CAN BE ACCESSED AT: [PSD Online Advanced Query](#)

Data source for oilseed table: OAA New Delhi historical data series. FAS New Delhi forecast for 2026/27; 2025/26 and 2024/25 are estimates.

Area Harvested and Production: For MY 2026/27, rapeseed acreage is expected to increase by two percent compared to MY 2025/26, achieving unprecedented production levels that solidify the crop's position as India's top-ranked oilseed. Market expectations for higher returns continue driving increased acreage and production. The adoption of improved high-yielding varieties combined with consecutive years of beneficial weather conditions has enhanced profitability, prompting farmers to allocate more land to this crop. Farmers continue benefiting from favorable prices around \$80 per quintal (\$800 per MT), up from the \$73-76 per quintal (\$730-760 per MT) range observed in MY 2025/26. Elevated prices are likely to continue motivating acreage and production increases for the outyear.

For soybeans, harvested area is expected to fall by three percent in MY 2026/27 compared to MY 2025/26, as farmers shift to more profitable crops like corn and wheat. In Madhya Pradesh and Maharashtra, India's top soybean-producing states, anticipation of increased corn planting – driven by better returns and supported by government procurement prices aimed at meeting higher ethanol blending targets – is expected to account for much of this decline. Production is also expected to drop by three percent with reduced acreage with yields lowered to 0.92 MT/Ha. The 2026/27 marketing year would mark the second consecutive year in which soybeans rank as India's second-largest domestically produced oilseed, behind rapeseed. Agricultural diversification away from soybeans toward corn is intensifying and would likely continue in the outyear.

Peanut acreage is expected to expand by two percent in MY 2026/27 compared to MY 2025/26. This growth stems from farmers transitioning from cotton to peanuts due to better profit margins observed in MY 2025/26. Relatedly, peanut production is likely to rise by three percent to 7.8 MMT, attributed to farmers adopting high-yielding varieties. Several agricultural universities and research institutes throughout Gujarat continue developing improved peanut varieties that have enhanced yields over recent years. Continued research is expected to increase yields for the outyear, sustaining production growth despite modest acreage expansion.

For cottonseed, a two percent decline in harvested area is anticipated in MY 2026/27 compared to MY 2025/26. Producers would likely pivot toward alternative crops such as corn and wheat given cotton's comparatively weaker price outlook. Consequently, cottonseed output is projected to drop one percent to 9.9 MMT. Revised production estimates for MY 2025/26 and MY 2024/25 reflect the shift from cotton to peanut cultivation, driven by more favorable peanut prices and adequate soil moisture conditions.

Copra oilseed harvested area is expected to reach 2.2 MHa for MY 2026/27, representing a modest increase from MY 2025/26. However, production is expected to remain stable at 935 thousand metric tons (TMT), comparable to current output levels. The Indian government

increased the minimum support price for copra by four percent for the 2026 season, aiming to enhance farmer profitability and encourage expanded production to meet rising demand for coconut-based products. This price adjustment has motivated farmers to expand planted area. However, since coconut palms require over five years to reach productive maturity, the impact on output will not be immediate. Key coastal producing states such as Kerala and Tamil Nadu continue grappling with low productivity rates, limited available acreage, significant import dependence, and diminishing yields from older plantations. For sunflowerseed, India's pattern of producing small but stable crops is expected to continue, with no significant changes anticipated in the outyear.

Crushing, Food Use, and Feed Consumption: FAS New Delhi projects total oilseed crushing for MY 2026/27 at 34 MMT, remaining steady compared to MY 2025/26. This stability reflects the combined effects of seed availability and market prices, as current price levels may not fully cover crushers' operational and capital costs. To meet domestic oil demand, India is expected to continue relying on competitively priced soybean oil imports. At the same time, increased production of peanuts and rapeseed is likely to boost processing of these crops. For the livestock and poultry sectors, demand for oilseed meal will increasingly shift to lower-cost feed alternatives such as distiller's dried grains with solubles (DDGS) and de-oiled rice bran, which are more available due to the growth of India's grain-based ethanol blending program.

Industry stakeholders continue to report that India has a total installed oilseed processing capacity of 50 MMT, with about 150 operational soybean crushing plants accounting for over 30 MMT of this capacity. Major processors, mainly large fast-moving consumer goods companies, adjust their capacity use based on domestic demand for soybean oil and meal. Profitability and comparative margins are driving operations, with facilities achieving better returns when they process multiple oilseeds and integrate value-added products like soy flour, tofu, and tempeh. As a result, aggregate crushing activity is likely to remain well below maximum capacity in the outyear (see Figure 2).

For MY 2026/27, soybean processing is anticipated to decrease compared to MY 2025/26, as narrow price margins limit profitability for crushers and processors. In contrast, rapeseed processing is expected to rise by two percent to 10.9 MMT, meeting India's growing edible oil needs more cost-effectively. Rapeseed oil remains popular in regional Indian cooking for its distinctive flavor. Steady consumer demand is expected to continue for both soybean and rapeseed oilseeds for direct food use, and feed waste utilization is likely to remain unchanged, with producers continuing to reserve these materials for seed retention and livestock feed.

For cottonseed, FAS New Delhi projects crushing to decline one percent to 8.8 MMT, tracking the production decrease. In contrast, peanut crushing is expected to rise two percent compared to the current year, driven by growing demand for both food and animal feed applications. Peanuts

have gained widespread popularity as household snacks throughout India, consumed both in-shell and shelled. Indians incorporate peanuts into numerous savory preparations and snack foods. Additionally, feed usage is anticipated to surge nine percent as producers in Gujarat and Rajasthan—the primary cultivation zones—increasingly utilize peanut meal for livestock feed. FAS New Delhi does not expect change in cottonseed feed use, as industry contacts indicate sustained demand from the livestock and fertilizer sectors for this oilseed.

Copra crushing is expected to remain stagnant at 900 TMT in MY 2026/27. The production of premium coconut products—including virgin coconut oil, desiccated coconut, and coconut milk—is anticipated to reduce copra availability for crushing operations. Furthermore, rising coconut oil prices are expected to constrain the supply of mature nuts available for copra processing. A substantial production and supply constraint has emerged, driving coconut oil prices upward and increasing import expenses in MY 2025/26. It is anticipated the same trend will continue for the outyear. Copra consumption for food and feed purposes is likely to mirror MY 2025/26 levels, reflecting persistent stagnation in demand observed in recent years. For sunflowerseed, minimal crushing is expected to continue, reflecting stagnant production forecasts. Additionally, sunflowerseed consumption for food and feed is likely to remain steady at MY 2025/26 levels, given stable demand in recent years.

Figure 2: Production and Crushing (TMT) – Marketing Year 2026/27 (Forecast)

Source: FAS New Delhi Research

Trade and Stocks: FAS New Delhi forecasts India's soybean imports to remain stable at 200 TMT for MY 2026/27, matching estimated MY 2025/26 levels, assuming an average crop in key African nations, particularly Benin, Niger and Togo—the primary supplier of non-GMO soybeans to India under least developed country (LDC) provisions with zero tariff rates. Indian

soybean imports predominantly originate from LDC-classified nations enjoying duty-free access. This arrangement benefits Indian processors when domestic soybean meal demand stagnates while soybean oil is largely imported through alternative channels.

FAS New Delhi also anticipates soybean ending stocks will decline by 42 percent, leading to a 16 percent decrease in total oilseed inventories for MY 2026/27. This drawdown reflects lower supply and continued demand. It is expected that farmers will respond to deteriorating profit margins by reducing soybean production and switching to other profitable crops like corn and pulses. Also, increased soybean oil imports exert downward pressure on prices and have eroded soybean's comparative advantage relative to alternate crops. Furthermore, the influx of soybean oil imports is shifting the domestic supply curve, lowering the equilibrium price for domestically produced soybeans and further reducing producer incentives. However, growing international demand for non-GMO Indian soybean meal—particularly for crush-to-oil applications—is boosting derived demand for soybeans, and is expected to lead to the drop in stocks.

For MY 2025/26, import estimates have been revised to 200 TMT, reflecting industry expectations of an average harvest in key African suppliers –Benin, Niger, and Togo – that will allow for exportable supplies to India. By contrast, imports in MY 2024/25 declined due to reduced production in these suppliers and higher export prices.

FAS New Delhi forecasts a modest uptick in India's peanut exports for MY 2026/27 relative to MY 2025/26 estimates. India's Agricultural and Processed Food Products Export Development Authority has promoted peanut exports and secured assistance from the Standards and Trade Development Facility to address aflatoxin contamination issues and ensure compliance with international market standards.

For rapeseed, trade volumes are expected to remain at zero and inventory levels are likely to hold steady at 569 TMT in MY 2026/27, reflecting balanced growth in both production and processing demand. Likewise, copra trade is expected to remain stable, with stocks forecast to hold at 12 TMT based on steady production patterns.

FAS New Delhi expects cottonseed ending stocks to decline 15 percent in MY 2026/27, from 325 TMT in MY 2025/26 to 275 TMT. This inventory reduction reflects lower production and processing volumes, combined with steady direct feed demand from both livestock operations and the fertilizer industry, in line with regional market preferences. Minimal sunflowerseed trade is projected, and ending stocks are anticipated to remain unchanged, given continued stagnant production and demand patterns.

OIL MEALS

India's oilseed meal production for MY 2026/27 is forecast at approximately 20.1 MMT, a marginal decrease from the current year (see Table 8). This outlook reflects ongoing changes in India's feed sector, where soybean meal's traditional dominance is expected to continue to erode in the face of growing availability and cost competitiveness of alternative feed ingredients—particularly DDGs from corn and rice, and de-oiled rice bran (DORB). Despite expectations of higher overall crushing, India is expected to produce less oil meal primarily because domestic soybean production is anticipated to fall. Soybeans have a relatively higher average meal conversion rate compared to other key oilseeds produced in India. Even with increased crushing of other oilseeds, such as rapeseed and peanut, their lower meal conversion will not offset less soybean meal.

Data source for oilseed table: OAA New Delhi historical data series. FAS New Delhi forecast for 2026/27; 2025/26 and 2024/25 are estimates.

Production: Soybean meal output is projected to decline by two percent in MY 2026/27 to 7.4 MMT, as demand continues to be displaced by more affordable DDGs and DORB. Soybean meal maintains a price premium over these alternatives, and this differential is expected to persist, further constraining its use in feed rations (see Table 16). Since 2023/24, India has restricted DORB exports to ensure adequate livestock feed, causing inventory buildup and prices to fall. Surplus DDGs from increased corn and broken rice use for ethanol blending further pressured prices. This year, DDGs prices have strengthened due to livestock feed demand but still remain below soybean meal prices.

Table 16: Feedstock Prices (US\$ per MT)

Feedstocks	MY 2025/2026	MY 2024/2025
Soymeal	475-500	315-335
DDGs from corn	230-240	221-233
DDGs from rice	310-333	310-325
De-oiled rice bran	165-175	148-152
Rapeseed meal	260-290	188-200
Peanut meal	280-400	278-390

Source: FAS New Delhi Research

Conversely, rapeseed meal production is forecast to increase by two percent to 6.5 MMT in MY 2026/27, supported by robust demand from both domestic and export markets. Rapeseed meal

remains competitively priced relative to soybean meal (trading at \$260–290/MT versus \$475–500/MT for soymeal), and its use is expanding in feed rations, particularly in regions where cost sensitivity is high. The expansion of rapeseed crushing capacity and favorable pricing are expected to sustain this growth.

Peanut meal output is projected to rise by three percent to 1.8 MMT, driven by increased peanut crushing and strong demand for cost-effective, high-protein feed ingredients, especially in Gujarat and Rajasthan. Cottonseed meal production is forecast to decline moderately to 4 MMT, reflecting reduced crushing and lower meal conversion rates. Copra and sunflowerseed meal production are expected to remain stable, with copra meal demand met primarily through imports from Indonesia and the Philippines.

Feed, Industrial, and Food-Use Consumption: Soybean meal feed consumption is forecast at 5.6 MMT for MY 2026/27, a seven percent decline from the current year. This reduction is driven by the increased use of DDGs and DORB in feed rations, a trend accelerated by India's expanding ethanol blending program. The poultry sector, which accounts for most oilseed meal demand, is expected to continue shifting to these more economical alternatives, resulting in slightly higher soybean meal stocks. In contrast, rapeseed and peanut meal consumption are expected to rise, reflecting their favorable pricing and nutritional profiles. These meals are increasingly incorporated into poultry and dairy feed, particularly in major producing states. The feed industry is also advocating for greater use of high-protein meals to meet the nutritional needs of India's growing population and expanding livestock sector. With GDP growth projected at nearly seven percent for 2026/27, demand for animal protein is expected to remain strong, further supporting meal consumption

Copra meal feed utilization is projected to grow by one percent, driven by regional feed preferences in coconut-producing areas. Cottonseed and sunflowerseed meal consumption are expected to remain stable, with demand shaped by relative pricing and the availability of alternative feedstocks.

Trade and Stocks: Soybean meal exports are forecast to increase by 13 percent in MY 2026/27, supported by continued demand for non-GMO Indian meal in Europe and China, and industry reports of improved trade relations with Bangladesh. Rapeseed meal exports are projected to rise by ten percent, with China expected to remain the top importer and expectations of Bangladesh increasing purchases if geopolitical conditions improve. Peanut meal exports are expected to remain steady, benefiting from proximity to key markets in South and Southeast Asia

FAS New Delhi increased the current year's export figures by four percent to reflect strong Chinese demand for Indian rapeseed meal, which has stabilized the market. In MY 2024/25, China purchased 500 TMT, making it the top importer. From October to December 2025, China

imported 163 TMT—the highest for that period. As a result of higher exports, ending stocks are reduced by 12 percent from the initial estimate.

Ending stocks for soybean meal are forecast up by six percent, reflecting reduced feed consumption and increased availability of alternative meals. Rapeseed meal stocks are expected to remain stable, while copra and sunflowerseed meal stocks are projected to be negligible due to steady demand and limited domestic production. Cottonseed meal stocks are expected to remain unchanged, with imports rising slightly to offset lower domestic output.

For minor meals, in MY 2026/27, copra meal exports are expected to remain negligible, while imports are forecast three percent higher at 185 TMT, primarily from Indonesia and the Philippines. Current year imports have been revised to 180 TMT due to favorable weather in the Philippines, which boosted shipments to India. Cottonseed meal exports are expected to decline by 20 percent because of lower production, while imports will rise five percent to 20 TMT; ending stocks remain stable. Sunflowerseed meal imports are projected to hold steady at 6 TMT, revised down from the current and previous years, with unchanged ending stocks due to sufficient alternative meal supplies.

OILS

India's total vegetable oil production for the 2026/27 marketing year is forecast at 9.5 MMT, a slight increase from the current year. This outlook reflects ongoing adjustments in India's edible oil sector as traders and processors respond to global price dynamics, evolving supply chains, and domestic policy changes. While total oilseed production is projected to decline (see Table 1), aggregate oil output is expected to rise (see Table 17) because the reduction is concentrated in soybeans, which have a relatively low average oil extraction rate of 0.18 (see Table 21). Increased production and crushing of higher-yielding oilseeds—such as coconut (0.63), rapeseed (0.38), and peanut (0.33)—more than offset the soybean shortfall, supporting overall growth in vegetable oil production.

Data source for oil table: OAA New Delhi historical data series. FAS New Delhi forecast for 2026/27; 2025/26 and 2024/25 are estimates.

Production: Soybean oil production is projected to decline by two percent to 1.7 MMT in MY 2026/27, due to a drop in availability of beans for crushing activity. Domestic edible oil requirements will be met primarily through increased imports of soybean oil expected from South America and China. The government's reduction of import duties on crude edible oils from 27.5 percent to 16.5 percent in 2025 is extended into 2026 as well and is expected to further encourage inflows of soybean and sunflower oils in the outyear.

Rapeseed oil production is forecast to rise by two percent to 4.2 MMT, supported by high-yielding seed varieties, and improved pod development. Peanut oil production is expected to increase by four percent, reflecting expanded crushing capacity and robust demand from both domestic and export markets, particularly China. Coconut oil output is projected to remain flat at 573 TMT, as persistent high copra prices and plantation maturation limit growth. Palm and sunflower oil production are forecast to remain stable at 305 TMT and 36 TMT, respectively, with palm oil cultivation initiatives expected to yield significant results only after 2028. Cottonseed oil production is expected to decline by three percent due to reduced cotton oilseed supply for crushing.

Food and Industrial Consumption: Despite an expected decline in domestic production, soybean oil consumption in 2026/27 is forecast to rise by about three percent, driven by increased imports of relatively cheaper soybean oil. Reflecting strong domestic demand and limited palm oil supplies through much of 2025, soybean oil consumption estimates for 2025/26

have been revised upward to 7 MMT. India continues to import around 60 percent of its edible oil needs, with palm oil historically accounting for the largest share, followed by soybean and sunflower oils. In 2024/25, higher palm oil prices—resulting from biodiesel mandates in Malaysia and Indonesia—shifted demand toward more affordable oils, though palm oil prices stabilized by late 2025. While Chinese soybean oil exports to India temporarily reduced demand for other oils, surplus palm oil inventories and falling prices have since restored palm oil’s market advantage, prompting a 17 percent upward revision in current year consumption estimates. For 2026/27, this trend is expected to continue, with palm oil consumption forecast to grow by two percent, supported by competitive pricing, reduced sunflower oil imports, and increased global supply following Indonesia’s export policy, which subsidizes biodiesel through palm oil export levies and boosts palm oil availability for export.

Consumer price inflation is expected to remain a significant factor, with projections around five percent for 2026/27. This will constrain discretionary spending and promote adoption of budget-friendly vegetable oils (see Figure 4). As domestic edible oil production falls short of demand, competitively priced imported soybean and palm oils are expected to gain traction. Industry sources expect supplies of sunflower oil from Ukraine to diminish due to an anticipated decline in the 2026/27 sunflower harvest, with Russia and other European nations partially offsetting the shortfall. Abundant soybean crushing from key suppliers are likely to fill the void in the Indian market.

Sunflower oil consumption is projected to grow by three percent, despite supply constraints from major exporters Ukraine and Russia. This growth reflects demand from India’s expanding population, forecast to reach approximately 1.5 billion by 2026/27. Peanut oil consumption is expected to increase modestly, while coconut oil usage will remain flat due to stagnant copra output. Cottonseed oil consumption is expected to fall by three percent, with industrial applications holding steady at 50 TMT.

Figure 4: Vegetable Oil Food Use, 2026/27 forecast

Source: FAS New Delhi Research

Trade: In 2025, the Indian government lowered import duties on crude edible oils from 27.5 percent to 16.5 percent. This will continue to be effective in 2026. This policy change forms part of the government's strategy to control rising retail oil prices and reduce inflationary pressure. The reductions should encourage greater imports and strengthen crude oils' competitive position in India's market (see Figure 5). Furthermore, with anticipated reductions in Ukrainian sunflower acreage and increased freight costs, soybean oil import growth should continue during the forecast period. Additionally, China is expected to continue to be one of the major exporters in 2026/27.

Soybean oil imports are forecast to rise by two percent, supported by competitive pricing from Brazil, Argentina, and China. India's procurement strategy is diversifying, with record imports from China driven by surplus conditions and competitive pricing. Sunflower oil imports are projected to remain at 2.2 MMT, but import patterns are shifting as buyers pursue more economical alternatives.

Industry sources expect palm oil production to decline in Malaysia and Indonesia in the coming year. Despite this, India's palm oil imports are projected to rise by three percent, driven by favorable prices compared to sunflower oil and limited supply from traditional sunflower oil exporters. Earlier in 2025, high palm oil prices led India to increase purchases of Chinese soybean oil, resulting in surplus palm oil stocks. As palm oil prices fell below soybean oil by late 2025, Indian palm oil imports surged, particularly in January 2026. This trend is expected to continue through the first half of 2026/27.

Rapeseed oil imports are anticipated to surge by 50 percent, with the United Arab Emirates and Russia emerging as principal sources. Peanut oil exports are expected to increase by eight percent, with China remaining the primary destination. Cottonseed and coconut oil trade volumes are projected to remain stable, supported by sustained demand from Middle Eastern markets.

Figure 5: India: Edible oil imports 2022/23, 2024/25 and 2025/26 (October to February)

Source: FAS New Delhi Research and Trade Data Monitor

Stocks: India’s edible oil inventory landscape for 2026/27 reflects strategic market positioning amid evolving global supply dynamics. Soybean oil and palm oil stocks are projected to remain substantial at 1.7 MMT and 1.9 MMT, respectively, providing supply security and price stability. Sunflower oil inventories are expected to decline by 11 percent to 470 TMT, reflecting reduced import volumes and steady consumption demand. Mid-tier oil stocks—rapeseed oil at 390 TMT, peanut oil at 240 TMT, and coconut oil at 102 TMT—are expected to remain stable, supported by balanced supply-demand dynamics.

Overall, India’s edible oil stock management demonstrates a deliberate strategy to leverage competitive global pricing, diversify supply sources, and maintain adequate inventories to buffer against supply disruptions. The inventory composition favors cost-effective oils—soybean and palm—while reducing exposure to premium-priced alternatives like sunflower oil, reflecting market responsiveness to price signals and supply availability.
