

Required Report: Required - Public Distribution

Date: April 09, 2025

Report Number: UK2025-0012

Report Name: Oilseeds and Products Annual

Country: United Kingdom

Post: London

Report Category: Oilseeds and Products

Prepared By: Jonathan Little

Approved By: Alexandra Baych

Report Highlights:

Marketing Year (MY) 2025/26 is forecast to see record low plantings of rapeseed oilseeds (rapeseed) in the United Kingdom (UK), down below 250 thousand hectares, with production falling below 750 thousand metric tons. Growers have become disillusioned with rapeseed after suffering from low yields, poor growing conditions, and pest pressures in previous years and have consequently turned to alternative land uses with more reliable returns, such as guaranteed contractual payments from UK agri-environment schemes. Recovering livestock numbers in MY 2025/26, particularly for pigs and poultry, are forecast to drive higher feed demand for both rapeseed and soybean meal.

Disclaimer: This report presents Post’s first outlook for oilseeds and products, and Production, Supply and Distribution (PSD) forecasts for the Marketing Year (MY) 2025/26, as well as estimates for MY 2024/25 and the historical context of MY 2023/24. Unless stated otherwise, data in this report is based on the views of Foreign Agricultural Service analysts in the UK and is not official USDA data. USDA official numbers in this report include the World Agricultural Supply and Demand Estimates (WASDE) March 2025 release.

Trade figures are revised according to the most recent data available from Trade Data Monitor (January 2025).

Abbreviations used in this report:

EU	European Union
FAS	Foreign Agricultural Service
Ha	Hectares
MMT	Million Metric Tons
MT	Metric Ton (1000 kg)
MY	Marketing Year
CY	Calendar Year
TMT	Thousand Metric Tons
TY	Trade Year
UK	United Kingdom
U.S.	United States

The marketing years used in this report are:

January - December

Palm kernel meal / oil

Palm oil

July - June

Rapeseed complex

October - September

Soybean complex

Sunflower complex

Peanuts

Executive Summary

In Marketing Year (MY) 2025/26, United Kingdom (UK) rapeseed oilseed production is forecast to fall below 750 thousand metric tons (MT), a further decline from the record low production levels last year. This forecast is based on record low plantings, with harvested area expected to fall below 250 thousand hectares, due to growers increasingly choosing to fallow land in agri-environment schemes instead of risking low margins from a poor yielding rapeseed crop (see Policy section). In MY 2025/26, crop conditions and yields are expected to be better than last year, even though pest pressures, particularly pigeon damage, caused some deterioration over the winter.

With domestic production in MY 2024/25 constituting less than half the domestic supply, the UK is forecast to become even more reliant on imports of rapeseed to feed crushing facilities. In MY 2025/26, imports are forecast to only partially compensate for domestic production declines due to lower profit margins for crushing imported rapeseed and other practical challenges linked to accommodating larger volumes of imports. Higher feed demand for rapeseed meal is forecast for MY 2025/26, returning above 1.3 million MT (MMT) due to anticipated increases in livestock numbers, particularly for pigs and poultry.

Recovering livestock numbers will also drive increased demand for soybean meal in MY 2024/25 and MY 2025/26, boosting demand for domestically produced soybean meal and imported soybean meal to meet increased feed requirements. Argentina remains the key exporter of soybean meal to the UK market, with almost 45 percent of market share, due to its price competitiveness and high protein content.

The UK government's guaranteed payments to contracted farmers in England under their agri-environment schemes have contributed to record low plantings of rapeseed over the last two years. In March 2025, the UK government announced its decision to close the base-level agri-environment scheme to new applications, while continuing to fund those farmers whose applications have already been accepted, for their three-year agreement term. For this reason, there is likely to be limited impact from the closure of this payment scheme on MY 2025/26 rapeseed production, but it could be more significant in the future.

Rapeseed – Oilseed

Production

In MY 2025/26 plantings of rapeseed oilseed (rapeseed) are forecast to fall by 20 percent and dip below 250 thousand hectares due to growers' pessimism of returns on rapeseed cropping and decisions to participate in guaranteed agri-environment payment scheme contracts (as described in the Policy section below), which require land to be used for wildflowers or remain fallow. In MY 2024/25, rapeseed production has suffered from low yields, poor growing conditions, and pest pressures, which has lowered grower confidence in rapeseed as a break crop from cereals (wheat/barley/oats). While rapeseed prices improved slightly in the second half of Calendar Year (CY) 2024, this rise in prices is insufficient to reverse growers' decisions. Based on forecasted lower plantings for MY 2025/26, production is expected to continue to fall, with it forecast to drop below 750,000 MT. Domestic production now constitutes less than half of the overall supply in the UK, with imports taking an increasingly dominant share due to stable domestic demand for rapeseed derivative products.

At the time of writing, crop condition reporting suggests that around 57 percent of the UK's winter rapeseed crop is rated in good or excellent condition. This is a marked improvement on the scoring of the MY 2024/25 crop at the equivalent point in the season. However, the Agriculture and Horticulture Development Board noted that crop conditions for rapeseed from the prior market conditions report have dropped from 73 to 57 percent over the winter due to pest pressures particularly from pigeon damage. This is reflected in the difference between forecast plantings and harvest areas for MY 2025/26.

Consumption

The UK primarily utilizes rapeseed for crush byproducts, specifically rapeseed meal and rapeseed oil. Rapeseed oil is a high-end product for use as a consumer ready frying/cooking oil and the most important usage for rapeseed in the UK. The UK's annual consumption of rapeseed is expected to fall well below 2 million MT (MMT) in MY 2024/25, with crushing anticipated to slow in the second half of the year due to limited supply. In MY 2025/26, domestic consumption is forecast to plateau with imports only partially compensating for expected domestic production declines due to lower crush margins on imported rapeseed and other challenges discussed in the rapeseed meal section below.

Trade

The UK was historically a net exporter of rapeseed. However, a ban on the use of neonicotinoid chemicals has made domestic rapeseed production challenging and made the UK more reliant on imports, with the UK becoming a net importer in MY 2017/18. For MY 2024/25, the combination of the significant reduction in plantings and low yield has increased demand for imports to compensate for reduced domestic production. Between July 2024 and January 2025, the UK imported almost 600,000 MT, up 12 percent compared to the 534,000 MT in the same period in MY 2023/24. Most of these additional imports have come from Ukraine, up around 74,000 MT to 346,000 MT and already above Ukraine's total exports to the UK in MY 2023/24. Imports from Ukraine have displaced European Union (EU) imports, which have reduced by 13 percent compared to the first seven months of the MY 2023/24 due to lower prices and a tight supply. A further ramp up of imports is anticipated in the remainder of the marketing year to meet demand, totaling around 975,000 MT for MY 2024/25.

Rapeseed meal

Production

In MY 2024/25, production of rapeseed meal is forecast to decrease by 9 percent, to approximately 970,000 MT with crush margins at their lowest in the last four years as UK oilseed crushers face lower domestic production, higher costs associated with imported rapeseed, and high energy costs. This has caused some crushing facilities to reduce operations and concentrate production in other facilities. Crush margins for domestically produced rapeseed are higher than imported rapeseed when taking into account freight costs, capital investment, and additional labor required to load and unload bulk grains from port to the crushing facilities. To date overall port capacity has not presented a constraint for imports.

The UK's largest crush plant on the Thames Estuary was not designed to be so reliant on imported seed. Crush volumes will largely be a function of crush margins, with these in turn dependent on rapeseed supply and demand for products. While supply outlook is currently good, there remains a risk that increased costs of imports and availability of alternatives (e.g. soy) squeezes rapeseed crush margins, hence the lower estimates for crush volume in 2024/25 and a similar forecast for 2025/26. Domestic production of rapeseed meal is not forecast to bounce back in MY 2025/26, with imports of meal instead satisfying feed consumption demand.

Feed Consumption

The UK livestock sector is the primary demand driver for rapeseed meal. The UK is a major producer and exporter of meat and dairy products. For MY 2024/25, the beginnings of a recovery in pig numbers are not thought likely to offset the anticipated reduction in the dairy cow herd, leading overall to an expected lower feed demand for rapeseed meal. Rapeseed meal can be substituted with soybeans and soybean meal, domestic sunflower meal, and other grains in feed formulations, depending on global prices. In dairy production, rapeseed meal has become the dominant feed ingredient as an affordable alternative to soybean meal. For poultry and swine production, soybean meal remains the top choice in feed ratios. Market volatility for feed ingredients is the main driver for substituting meals, and while global soybean supplies are anticipated to be high, it would take a significant discount in the price of soya to squeeze rapeseed meal out of the market. For MY 2025/26, higher feed demand for rapeseed meal is forecast, with it returning above 1.3 MMT due to anticipated increases in livestock numbers, particularly for pigs and poultry albeit with more uncertainty with cattle numbers.

Rapeseed Oil

Production

Demand for rapeseed oil is the main driver for the rapeseed market in the UK. The UK predominately produces oil for food use with a small, but stable, quantity for industrial use. In MY 2024/25, rapeseed oil production is expected to reduce sharply, principally due to the low availability of domestically produced rapeseed, insufficient imports to fill the gap, and the reduced crush volume, with production levels forecast to stabilize in MY 2025/26.

Consumption

Demand for rapeseed oil remains high and is expected to grow in the coming years, in part due to a shift away from alternatives, like palm oil, perceived as less sustainable options. In MY 2024/25, continued strong domestic food use consumption is expected to lead to increased import volumes, with similar levels forecast in MY 2025/26, to compensate for reduced domestic production. Between July 2024 and January 2025, the majority of imports had come from the Netherlands, Germany and Belgium, with the EU accounting for almost all the trade supply. Over those same seven months, exports are down by more than half, indicative of the tightness in the market. Industrial consumption remains a small but stable part of UK consumption.

Soybean Seed

Consumption and Trade

The UK's soybean imports are predominately used for crushing, food use, and livestock feed. The largest supplier is Brazil, feeding the primary UK crush facility, which is located in North-West England, between March and October. Imports from the United States and Canada supply the same plant between November and February, with 60,000 MT of Ukrainian soybeans also coming in during MY 2023/24. For MY 2024/25, industry contacts confirm that the New Post figure for crush volume is more accurate, with total domestic consumption amended accordingly.

Imports for MY 2024/25 and MY 2025/26 are likely to approach the 1 MMT, getting close to the crush plant's maximum capacity. In the first four months of MY 2024/25, imports from Canada have already reached 185,000 MT, compared to 3,000 MT in the same period in MY 2023/24, with this spike based on price and the navigability of the shipping routes. Imports from the United States are still expected to reach around 200,000 MT for the full marketing year, despite data for the first four months of MY 2024/25 being 93 percent down (at 132,000 MT) on the same period last year. For MY 2025/26, imports from the United States are expected to come online earlier than normal, assuming trade remains stable.

The crush volumes and domestic consumption are expected to be largely static between MY 2024/25 and 2025/26, reflecting the relative stability of the market. The UK has also prioritized sustainability policies and end-user preferences, including with regards to soybean products. For this reason, in MY 2025/26 there may be some movement towards prioritizing imports from North American origins.

The 'just-in-time' nature of the crushing operation means that soybean storage in the UK is limited to little more than two weeks' of crushing volume, with this reflected in the stocks figures below.

Soybean imports compete with rapeseed in the livestock feed sector dependent on input costs and protein content. In terms of their relative competitiveness in MY 2025/26, the tightness in the global rapeseed market – while eased slightly compared to the previous year – is expected to leave space for growth in soybean imports to the UK.

Soybean Meal

Consumption and Trade

Argentina remains the key exporter to the UK market, with almost 45 percent of the market share, due to its price competitiveness and high protein content. Brazil has traditionally been the second largest supplier, but a significant (28 percent) reduction in exports in MY 2023/24 meant it was overtaken by Paraguay and the United States in volume traded. In the first four months of MY 2024/25, Brazil regained its second spot in terms of market share.

Demand for soyabean meal will likely increase in MY 2024/25 and MY 2025/26 as a result of recovering livestock numbers, particularly for pigs and poultry, with the increased domestic production of soybean meal and higher import volumes being absorbed by this extra feed consumption. In MY 2025/26, soybean meal imports are forecast to reach over 2 MMT but remain below MY 2024/25 rates based on prior year carryover stocks.

As noted earlier, rapeseed meal and soybean meal are substitutable feed inputs for the livestock sector. In MY 2024/25 and MY 2025/26 domestically produced rapeseed meal and rapeseed meal imports are

not expected to rise significantly compared to prior years and coupled with the soybean crushing facilities operating close to maximum capacity, this provides additional opportunities for growth in soybean meal imports to the UK in MY 2024/25 and MY 2025/26.

Soybean Oil

Consumption and Trade

UK soybean oil imports and food use remain strong while industrial use is now around 25,000 MT per year as UK biofuel production focuses mainly on grain and corn. This focus will, however, be constrained by the commitment in the UK government's [Renewable Transport Fuel Obligation](#), which has set a cap on the crop-based contribution of biofuels, with that maximum level decreasing on a linear path from four percent initially down to two percent by 2032.

Any fluctuation in domestic soybean crush is met by imports of soybean oil, almost entirely from the EU and Norway providing the readily available supply of non-genetically engineered soybean oil demanded by UK retailers.

Consumption and Trade

As noted in last year’s report, a suspected anomaly with the classification of peanut ‘seed’ imports from the United States in the trade data has created a deviation between the Post data and USDA Official numbers, with this again reflected in imports for MY 2023/24 and an associated divergence in food use consumption. For the first four months of MY 2024/25, this anomaly in the trade data, originally drawn attention to by market commentators, now seems to have been resolved, with ‘peanut seed’ imports back down to zero. Post figures in the table above reflect the division of overall domestic consumption between food and feed (i.e. birdfeed and pet food) uses.

Policy

As set out in our last UK [Oilseeds and Products Annual](#) report, there have been only a small number of areas the UK has sought to deviate from the EU. The UK has deviated from the EU on biotechnology application renewals and transitioning post-Brexit agricultural funding in England to agri-environment or environmental land management schemes. In relation to trade policy, the voluntary tariff suspension on sunflower-seed oil introduced at the start of 2023 due to supply chain disruptions caused by the war in Ukraine has been extended until at least the end of June 2026. (More information can be found in the GAIN report entitled '[Certain Voluntary Tariff Suspensions Extended to June 2026](#)'.)

Biotech Policy and Approvals

Following Brexit, the UK established an independent approval mechanism for genetically engineered (biotech) products but has lagged behind the EU in approving new events. As discussed in more detail in our latest [Agricultural Biotechnology Annual](#) report, the ever-growing backlog includes multiple soybean and canola events. This is providing an increasing impediment to imports of these products, including from the United States.

More positively, the UK government has taken steps to implement the Precision Breeding Act passed in 2023, by laying before Parliament the detailed regulations to commercialize precision-bred plants – defined as plants whose genetic makeup has been altered through changes that could also have occurred naturally or through traditional breeding methods, without the introduction of exogenous genetic material (see [GAIN report](#) for more details). Among the range of potential applications of this technology when it is authorized for use in England is pod-shattering resistance in rapeseed to reduce harvest losses.

Agri-Environment Options

As noted in last year's Oilseeds and Products Annual report, the roll out of the post-Brexit farming incentive schemes is also having an apparent impact on oilseeds production. In England, where over 90 percent of the UK rapeseed crop is grown, increased payment rates offered for actions contained in the Sustainable Farming Incentive (SFI) scheme is frequently cited as being a factor in the historically low plantings in the last two marketing years. The low yields and low profit margins for rapeseed is such that farmers would rather choose the SFI option rather than plant rapeseed. The SFI option can provide almost twice the returns compared to planting rapeseed. For this reason, domestic growers have turned to SFI options as an alternative break in their arable rotation given the balance of risk and reward.

On March 11, 2025, the Department for Environment, Food and Rural Affairs (Defra) announced abruptly that it would no longer accept new applications to the SFI scheme, as it had reached its funding limit for the current budget cycle. While all multi-year agreements already in place will continue, the absence of this SFI scheme may impact future rapeseed plantings.

Industry Campaign

In the face of the reduction in the area of rapeseed grown in the UK, industry groups have launched a 'Reboot Campaign' to raise the profile of the sector. The focus to the campaign's lobbying to date has been on the speed of pesticide product registrations and attempts to persuade Defra to introduce SFI

options that are compatible with the rapeseed crop, rather than outcompete it. When featured in the specialist farming press, the campaign's objectives have been conflated with critical observations about the UK's increasing reliance on imports that are grown with inputs banned domestically, particularly neonicotinoid seed treatments. When challenged on the UK's continued acceptance of imports produced using neonicotinoids at the annual conference of the major domestic farming union in February 2025, the Defra Secretary of State, Steve Reed, pointed out that such treatments had been banned in the UK, before suggesting he was looking at what the government might do on trade as well.
