Date: January 09, 2026

Report Number: AR2025-0028

Report Name: Oilseeds and Products Update

Country: Argentina

Post: Buenos Aires

Report Category: Oilseeds and Products

Prepared By: Chase McGrath

Approved By: Chase McGrath

Report Highlights:

MY2025/26, Post forecasts Argentina's soybean production at 47.5 MMT, supported by favorable early season conditions despite planting delays from excessive rainfall, while MY2024/25 production remains estimated at 50.5 MMT. Soybean crush for both MY2024/25 and MY2025/26 is raised to 43.0 MMT on strong margins, robust meal demand, and sustained plant utilization, even as record soybean exports tighten domestic balances. Sunflower area is revised upward to 2.7 MHA for MY2025/26, with near record production expected and crush projected to reach an all-time high of 5.0 MMT amid new processing capacity and strong export demand. Peanut production declines in MY2025/26 due to sharply lower planted area following last year's record crop, though MY2024/25 exports are raised to 1.10 MMT on a strong shipment pace.

SOY

Production

As of publication, the total soybean crop was 82 percent planted, according to the Buenos Aires Grain Exchange, representing a delay of 12 percent points compared to the same point in the previous season. The majority of first-crop soybeans have already been planted. Planting of second-crop soybeans which are typically sown on wheat fields following harvest, is well underway, although progress has been slower in some areas due to heavy rains throughout December. Delays have been most pronounced in the “zona núcleo,” Argentina’s prime growing region, where persistent and heavy rains have slowed wheat harvest and, in turn, postponed second-crop soybean planting. This is especially true in Buenos Aires Province.

At this stage of the campaign, yield prospects for the MY2025/26 soybean crop are considered highly favorable, contingent on the continuation of current weather conditions. Producers report strong crop development, and some in prime growing areas indicate expectations of yields reaching as high as 4.0 tons per hectare. These expectations reflect the generally positive conditions and expectations for this season up to this point in the growing season.

Figure 1. First Crop Soy in Central Buenos Aires Province

Source: FAS Buenos Aires

First crop soy is already in excellent condition, with most of the second soy planting underway. Planting of some second soy has been delayed due to flooding or excessively muddy fields, but producers do not expect this to have a significant impact on overall production of the crop this year. Some weather-related risks could impact total production as conditions transition from a weak La Niña pattern toward a neutral pattern during the summer months. Favorable soil moisture levels, following an unusually wet fall and spring, have supported a bumper wheat crop spurring optimistic outlooks for both corn and soybeans. The summer is expected to begin under weak La Niña conditions before gradually shifting to neutral, but risks persist, including episodes of heat and dryness that could stress crops and pastures, localized

severe storms with heavy rainfall, wind, and hail, and uneven precipitation across regions. Looking further ahead in the season, according to the national weather service, the early activation of polar air masses in autumn 2026 could raise the risk of early frosts in some areas.

Source: Bolsa de Comercio de Rosario with FAS Buenos Aires Translations

From an economic perspective, producers are increasingly optimistic about profitability in the MY2025/26 campaign, expecting improved margins relative to the previous year. Current projections suggest that producers could be slightly profitable even on leased land. According to the Rosario Board of Trade, the estimated break-even yield is 4.1 tons per hectare for leased land and 2.8 tons per hectare for producer-owned land.

Figure 2. Argentina Soil Moisture as of December 25, 2025

Source: USDA FAS Crop Explorer

The [recent reduction in export taxes](#) on soybeans, which were lowered by two percentage points to 24 percent for soybeans, is not expected to have a significant impact on soybean planting decisions in the current season. Industry contacts indicate that further expansion of soybean area would require additional, significant reductions in export taxes. At present levels, export taxes continue to weigh heavily on producer returns and, in many cases, represent the margin between profitability and loss.

Figure 2. Soil Moisture in Buenos Aire Province

Figure 3. Soil Moisture in Santa Fe and Cordoba Provinces

MY2025/26

Post maintains its previous soybean production forecast for MY2025/26 at 47.5 million metric tons (MMT), which remains below the USDA official estimate. This outlook reflects producers’ intentions to return to more corn relative to soybeans compared to the previous season. Abundant rainfall continued immediately prior to and during the initial phase of first-crop soybean planting, contributing to generally favorable conditions for the early establishment of the crop, but conditions did not change significantly enough alter producers’ overall crop mix decisions.

Favorable soil moisture conditions, combined with well-timed rainfall events, have provided a strong foundation for early crop development across much of the core production area. These conditions reinforced generally positive yield expectations at this point in the season.

While localized flooding and excessive rainfall could still encourage some producers to shift acreage from late-planted corn into second-crop soybeans instead, particularly in areas where field access has been delayed, Post contacts reports indicate that most producers are sticking to their original planting intentions. As a result, Post does not anticipate significant late-season adjustments to soybean area.

From a cost perspective, higher production expenses pose a potential constraint on producer margins. Increased herbicide application in particular, driven by early weed pressure stemming from persistent moisture and elevated humidity, are expected to raise input costs and could erode profitability, especially for producers on leased land.

The MY2025/26 soybean planting is well under way in Argentina's core production region under generally favorable conditions, with adequate soil moisture reported on approximately 75 percent of fields and improved prospects relative to the previous year. Based on current harvest prices near USD 311 per metric ton, profitability improves compared with the previous year, particularly on producer-owned land, and farmers are targeting yields above 4.0 MT per hectare to achieve profitability. In addition, market volatility, lingering risks associated with potential La Niña-related weather stress, and expectations of a record Brazilian soybean crop are weighing on price outlooks, souring what otherwise would be enthusiastically optimistic producer sentiment.

MY2024/25

Post also maintains its previous MY2024/24 soybean production estimate of 50.5 MMT on a total planted area of 17.5 MHA. Post also maintains its nationwide yield average of 2.99 tons per hectare.

Consumption and Crush

Post raises its MY2024/25 soybean crush forecast by 1.0 MMT to 43.0 MMT. Post also increases its MY2025/26 crush forecast by 1.0 MMT, likewise to 43.0 MMT, matching the revised MY2024/25 level and aligning with USDA official estimates. Crushers report continued high demand and margins with crush expected to remain high for the remaining five months of the marketing year.

Soybean crush slowed in November 2025 compared with the previous month, totaling 3.49 MMT, down from 4.04 MT in October. Despite the month-to-month decline, October crush volumes were notably strong, rising 22 percent from September levels, which had marked the highest monthly crush of the calendar year. As a result, the November moderation is viewed more as a normalization following exceptionally strong crush rather than a slowdown.

Historically, processing activity tends to slow ahead of the new harvest. However, current margins continue to incentivize strong crush rates. Robust prices for soybean meal, coupled with favorable soybean oil prices, have sustained attractive processing margins and are expected to keep crush elevated in the near term. Additionally, should exports of whole soybeans slow in coming months, Post expects additional volumes to be diverted into domestic processing, further supporting high crush levels.

Argentina's soybean crush remains slightly below last year's pace despite a larger crop. In November 2025, soybean crush totaled 3.49 million metric tons, up 1.6 percent year-over-year; however, cumulative crush during the first eight months of MY2024/25 reached 30.7 million metric tons, down 1.2 percent from the same period last year, even as production increased by six percent. The slower pace of processing reflects strong incentives to export unprocessed soybeans driven by increased Chinese sourcing from South America following reduced purchases from the United States in recent months.

Official estimates place MY2024/25 soybean exports at 12.2 million metric tons, nearly triple the prior year. Crush activity rebounded in June following the restart of Vicentin-controlled plants and accelerated producer sales under temporary export tax reductions but declined again in July due to higher export duties and reduced farmer selling. Imported soybeans, primarily from Paraguay, remained critical to sustaining plant utilization, accounting for 13.2 percent of total crush during April to November, compared to 18.1 percent a year earlier, under Argentina's temporary import regime that requires re-export of processed products.

Meals and Oils

Post raises Argentina's soymeal import forecast for MY2024/25 to 510,000 metric tons, more than double the previous estimate, reflecting exceptionally strong year-to-date imports. As of the latest data, Argentina has already imported 389,454 metric tons of soymeal, almost entirely from Paraguay, with four months remaining in the marketing year, already well above the prior record for annual imports. This counter-seasonal increase in imports is primarily driven by Argentina's unusually high soybean export pace this year, which has constrained domestic meal availability. As a result, some soymeal is being imported to satisfy domestic feed demand, while locally produced soymeal is directed toward export markets where prices are more attractive.

Post also raises soymeal export forecasts for both MY2024/25 and MY2025/26, driven by higher crush volumes and continued growth in global demand for protein meals. Strong international demand particularly from Asia and key livestock-producing markets, is expected to persist into the upcoming marketing year, sustaining Argentina's role as a leading global supplier of soymeal despite tighter domestic balances.

Figure 2. Soy Planted on Flooded Field in Central Buenos Aires Province

Source: FAS Buenos Aires

Trade

On December 9, the Argentine government announced another permanent reduction in export taxes (locally known as *retenciones*), marking the third such cut in 2025. The measure is consistent with the policy priorities and campaign promises of President Javier Milei, aimed at encouraging producer selling, improving the international competitiveness of Argentine agricultural products and accelerating foreign currency inflows to the Central Bank. Under the new framework, soybean export taxes were reduced to 24 percent, while soymeal and soy oil export taxes were lowered to 22.5 percent, each a two percentage point cut from previous levels. Unlike earlier temporary reductions, these changes are permanent, providing greater policy certainty to exporters and processors and reinforcing incentives for near term sales.

Post lowers MY2024/25 soybean import forecasts to 7.4 million metric tons, bringing estimates closer to, though still above, USDA official figures, reflecting a slower-than-expected import pace in recent months. Even with the downward revision, imports remain historically high and are expected to stay elevated through the remainder of the marketing year. Imports remain highly dependent on Paraguay's production outlook. A larger Paraguayan soybean crop would likely result in increased shipments to Argentina for crushing and subsequent re-export of soy products.

Soybean exports remained strong through October, November, and into December, despite already record export volumes earlier in the marketing year and concurrently high domestic crush rates. The combination of aggressive exports and crush is expected to result in tight ending stocks this year, with minimal carryover into MY2025/26.

Soybean exports reached a record 2.19 MMT in November, with 11.47 MMT exported year to date in the marketing year.

Looking ahead, Post expects soybean exports in MY2025/26 to return to more traditional levels for Argentina. However, geopolitical issues, namely the relationship between the United States and China could shift Argentina's export outlook. Argentina's export outlook for whole beans remains highly contingent on broader U.S. - China trade dynamics rather than domestic production or market factors. Post forecasts soybean imports to increase further in MY2025/26, supported by continued strong export demand and sustained high crush utilization in Argentina. As in the current marketing year, the ultimate level of imports will largely depend on Paraguay's crop size with a strong Paraguayan harvest resulting in additional soybean inflows to Argentina, further supporting crush margins and exportable supplies of soymeal and soy oil.

SUNFLOWER

Production

For MY2025/26, Post raises its sunflower planted area forecast to 2.7 million hectares, remaining well above USDA official estimates. The upward revision reflects larger than previously expected area reported in northern producing regions, where sunflower has regained competitiveness relative to alternative crops due to favorable margins and improved weather conditions at time of planting.

Sunflowers in Northern Buenos Aires Province

Source: FAS Buenos Aires

In recent years, dry weather in northern sunflower production areas prevented producers from achieving intended planting levels. In contrast, MY2025/26 benefited from timely and adequate rainfall during the planting window, allowing sunflower to be planted largely in line with initial producer intentions for the first time in several years. Improved soil moisture conditions before and after planting further supported strong early crop development.

Post forecasts near record sunflower production in MY2025/26, driven primarily by the expanded planted area both in the north and south, and favorable moisture availability at critical stages of crop establishment. While final yields will depend on weather conditions through the remainder of the growing season, early indicators point to strong production potential.

Harvest of the MY2025/26 sunflower crop has already begun in northern regions, with approximately 7 percent of total area harvested to date according to the Buenos Aires Grain Exchange, right on track from the same time the previous year. Early yields are being reported at record or near-record levels, solidifying expectations for a strong overall outcome for the current marketing year.

Post maintains its MY2024/25 sunflower production forecast at 5.0 million metric tons.

Consumption and Crush

Sunflower crush in Argentina is on track to reach a record high in the current marketing year, with 4.07 million metric tons already crushed through October on a calendar-year basis. Strong crush is driven by robust domestic and export demand for sunflower oil and meal, supported by ample available sunflowerseed availability and favorable crush margins.

Post maintains its MY2024/25 sunflower crush estimate at 4.2 million metric tons, slightly above USDA official forecasts. This estimate is supported by exceptionally strong crush volumes in September, October, and November, with processors expected to maintain above-normal utilization rates through the remainder of the marketing year as additional sunflower supplies come to market during harvest. Strong demand and higher expected production are projected to carry into MY2025/26. Post therefore maintains its sunflower crush forecast at 5.0 million metric tons, which, if realized, would represent the highest crush volume on record for Argentina. Continued expansion in processing capacity and improved producer confidence with planting sunflower underpin this forecast.

Investment and growth of sunflower in Argentina continues. A large domestic company recently completed a major investment to expand sunflower crush capacity at its facility in San Lorenzo, one of Argentina's primary oilseed processing hubs on the Parana river. The new line is expected to come online in January, in time to process part of the record sunflower crop and will add up to 500,000 metric tons of annual sunflower crush capacity. This marks the second major sunflower-processing investment in Argentina within the past year, underscoring renewed industry confidence in sunflower as a profitable and increasingly strategic oilseed for Argentina's oilseed sector.

Trade

Strong exports year to date positions MY2024/25 as the largest export year for Argentine sunflower products in more than 25 years. Shipments of sunflower seed, sunflower meal, and sunflower oil have all expanded significantly, supported by higher production, increased yields, improved competitiveness, and robust international demand, particularly for sunflower oil.

These favorable trade dynamics are expected to extend into MY2025/26, underpinned by forecasts for higher planted area and above average yields. Expanded crush capacity and sustained global demand for oils are expected to support continued growth in sunflower product exports in the coming marketing year.

Sunflower prices remain exceptionally strong, reflecting tight global supplies and firm demand. Spot market quotes in Rosario reached approximately USD 500 per metric ton during the week of December 11, providing strong price incentives for producers and reinforcing sunflower's improved competitiveness relative to other oilseeds.

Peanut

Production

MY2025/26

Post lowers MY2025/26 peanut planted area to 400,000 hectares, down 10,000 hectares from Post's previous forecast and a sharp 132,000 hectare decline from MY2024/25. The significant contraction reflects lower price expectations and a market glut following last year's record production, which weighed heavily on producer margins and planting intentions.

A notable share of producers entered peanut production for the first time in the previous marketing year, attracted by high prices at planting and low prices for other commodities. However, prices declined sharply by harvest with the increased planted area and production, deflating returns and optimism for the crop that started the season. Combined with the agronomic challenges associated with peanut production, including soil disruption and higher management costs, many first-time growers have opted to exit the crop in MY2025/26, contributing to the steep reduction in area.

Despite the smaller planted area, yields in MY2025/26 are expected to improve year over year, supported by generally favorable weather conditions and continued adoption of improved peanut varieties and genetics. As a result, while overall production is forecast lower due to reduced acreage, yield performance is expected to partially offset the decline and support more stable per-hectare returns for the remaining producers.

MY2024/25

Post raises MY2024/25 peanut planted area to 532,000 hectares, aligning with USDA official estimates and reflecting higher-than-previously reported plantings, particularly in core producing regions. Improved margins relative to competing crops and generally favorable early-season conditions supported the expansion in area.

Based on the larger planted area and high yields reported by growers, Post increases MY2024/25 peanut production to 1.86 million metric tons. Average yields are estimated at approximately 3.5 metric tons per hectare, reflecting good soil moisture availability and timely agronomic practices across much of the peanut belt.

According to the Buenos Aires Grain Exchange, planting progress is well underway, with 84 percent of the MY2024/25 peanut crop already planted. Crop conditions to date suggest solid yield potential though the final outcome will depend on weather conditions through pod filling and harvest in the coming months

Trade

Post raises MY2024/25 peanut exports to 1.10 million metric tons (in-shell basis), an increase of 50,000 metric tons from the previous forecast. The upward revision reflects a strong export pace to date, with approximately 704,000 metric tons already shipped and four months remaining in the marketing year, indicating exports are on track to exceed earlier expectations.

Higher export volumes have been supported by ample domestic supplies following this year’s large production and strong demand from key markets, particularly the European Union and Australia. Competitive pricing and Argentina’s established reputation as a reliable supplier of high-quality peanuts continue to support export demand, positioning Argentina for another strong year of exports despite emerging supply adjustments in the upcoming marketing season.
