Date: April 12, 2023

Report Number: AS2023-0005

Report Name: Oilseeds and Products Annual

Country: Australia

Post: Canberra

Report Category: Oilseeds and Products

Prepared By: Zeljko Biki

Approved By: Levin Flake

Report Highlights:

Australian oilseed production, dominated by canola, is expected to be strong again in marketing year (MY) 2023/24, but down from the record in MY 2022/23. Canola production is forecast in MY 2023/24 at 5.5 million metric tons (MMT), the third largest from the record-busting crop estimated at 8.3 MMT in MY 2022/23. Canola planted area and yields are expected to decline in the forecast year after setting a record in the previous year partly due to expectations of lower prices and drier seasonal conditions. Canola oil exports are forecast at 240,000 MT in MY 2023/24, a decline from the MY 2022/23 estimate, but if realized is still the second highest on record. Olive and olive oil production are forecast to decline in MY 2023/24, mainly as a result of a natural biennial effect on yield after a high previous crop. Cottonseed production is forecast to rise to the third largest on record with strong exports and crushing volume is expected to increase for the first time in five years.

EXECUTIVE SUMMARY

Australian oilseed production, dominated by canola, is expected to be strong again in marketing year (MY) 2023/24, but down from the record in MY 2022/23. Canola production is forecast in MY 2023/24 at 5.5 million metric tons (MMT), the third largest crop after an estimated record-busting 8.3 MMT in MY 2022/23, and 6.8 MMT in MY 2021/22. Farmers took advantage of great early seasonal conditions and very high canola prices by planting as much canola as they could for MY 2022/23. But now with far lower canola prices for the forecast crop, a decline in planted area is expected. Although there have been good fall rains for the start of planting for the MY 2023/24 crop and sub-surface soil moisture in general is around average, dry conditions are forecast. With this, the canola yield for the forecast crop is anticipated to be near average. Canola oil exports are forecast at 240,000 MT in MY 2023/24, an eight percent decline from the MY 2022/23 estimate, but if realized is still the second highest on record.

Olive and olive oil production, although a small contributor to overall Australian oilseed production, are forecast to decrease in MY 2023/24 due to a natural biennial effect on yield after a high previous crop. The long-term trend in Australia is for expanding olive production as young trees commence bearing fruit and maturing trees continue to increase yields.

Cottonseed production is forecast to rise by five percent in MY 2023/24 to Australia's third highest level. This is in part due to an anticipated increase in irrigated cotton planting contributing to a rise in the average yield. But a more substantial contribution is the assumption that more normal conditions will be experienced at planting, enabling the crop to be planted in a timelier and more optimal period, after a highly disrupted and extended planting period occurred for the MY 2022/23 crop. Cotton growers also have a high degree of confidence that there will be ample irrigation water available for an expanded irrigated cotton planting in the forecast year.

CANOLA

Production

FAS/Canberra forecasts canola production to decline by 34 percent to 5.5 MMT in MY 2023/24, but if realized this would still be the third largest crop ever, following the previous two years of successive records. Soil moisture conditions in the canola growing regions are generally good and there has been a strong start to fall rains in most regions. A further encouragement for farmers is that nitrogenous fertilizer prices have fallen substantially since the peaks around planting for the MY 2022/23 season. The last two years of exceptional rains and excellent commodity prices had resulted in farmers practically planting every available hectare to winter crops, with particular focus on additional canola. This included using areas that were earmarked for fallow and for some planting canola in the same field for two and even three successive years. A shift back to more typical rotation patterns, combined with canola prices falling back toward longer-term average levels, is resulting in farmers deciding to reduce their planted area of canola. Further to this, the Australian Bureau of Meteorology is forecasting a far-

below-average chance of achieving median rainfall in the coming months, which if realized will impact crop yields.

The harvested area of canola is forecast to decline by 15 percent in MY 2023/24 to 3.3 million hectares (Ha) which would still be the second largest on record (see Figure 1). This fall is due to farmers having less suitable area available in their crop rotations for canola after the previous two big-planted area years. Some farmers have planted canola in the same field for two and in some cases three successive years to take advantage of the great seasonal conditions in recent years and the very high canola prices. But this practice invites a higher risk of crop disease and many farmers for this current planting period will plant canola in other areas following a legume or cereal crop. In addition, after such a heavy winter cropping program over the previous two seasons, farmers will be reintroducing fallow areas into their crop rotations. Combined with increased fallow, this will reduce the available area for canola planting.

Figure 1 – Australian Canola Area Harvest History

Source: PSD Online / FAS/Canberra

Notes: (e) = estimate, (f) = forecast

Canola requires high nitrogen inputs relative to the other major winter grains, mainly wheat and barley, and a key positive for growers is that the price of imported nitrogen-based fertilizers has fallen from the peak of US\$770 per metric ton (MT) in May 2022, to below US\$500 at the start of 2023 (see Figure 2). The big spike in prices was attributed to the rising energy costs which commenced in 2021 and was further exacerbated by the Russian invasion of Ukraine, and also the restriction of supply from China also in 2021. The prices are still near double those in 2020 prior to these impacts, but there is scope for some further decrease in prices during the planting period.

Figure 2 – Average Monthly Nitrogenous Fertilizer Import Price Trend

Source: Australian Bureau of Statistics

Canola yields are forecast to be 1.67 MT/Ha, 14 percent above the previous 10-year average, but this is a 22-percent decline from the estimated MY 2022/23 season record of 2.13 MT/Ha. This is on the basis of good early rainfalls in the fall and generally good sub surface soil moisture available which mostly remains from the great rains experienced in the previous winter cropping season.

Rainfalls from mid to late March across the main canola growing regions have been very good (see Figure 3) with further rains forecast for early April 2023. Canola is typically planted from March to May and harvested from October to December. The more northern production areas generally have earlier planting and earlier harvest compared to the more temperate climate in the southern areas. Most of the canola growing regions have around average soil moisture this year, especially in the eastern growing regions, as planting approaches (see Figure 4). This will provide canola growers confidence that in conjunction with the good fall rains that the crop will not only germinate but will have ample soil moisture to establish well, even if there were to be limited rains in late fall and early winter as is forecast to be the case by the Australian Bureau of Meteorology (see Figure 5).

Figure 4 – Australia Soil Moisture Map – March 25, 2023

Source: Australian Bureau of Meteorology / FAS/Canberra

Figure 5 - Australia Rainfall Forecast Map – April to June 2023

Source: Australian Bureau of Meteorology / FAS/Canberra

Canola prices have fallen by over a third from the peak in 2022 of near AU\$1,000 (US\$675) per metric ton (MT) to now be at around AU\$600 (US\$445) per MT (see Figure 6). The current canola price is still firm and above longer-term average prices which will still encourage a very high planting area. However, as a higher risk crop to grow compared to cereal grains and with a lower-than-average rainfall outlook, the current canola prices will encourage farmers to more closely manage their winter cropping program risks compared the previous two exceptional seasons.

Canola production for MY 2022/23 is estimated to have achieved a third successive record at 8.3 MMT and is in line with the official USDA estimate and the Australian Bureau of Agriculture and Resource Economics and Sciences (ABARES) estimate, finishing well above earlier expectations at the commencement of harvest. This was far higher than the record set in the previous year of 6.8 MMT, due to both an increase in planted area and achieving a record national average yield. The estimated average yield of 2.13 MT/Ha is 44 percent higher than the previous five-year average (see Figure 7). Unusually for a second successive season, despite the diverse area in which canola is grown in Australia, nearly all regions had particularly good growing condition throughout the season which supported yet another extraordinary high average yield, slightly above the 2.1 MT/Ha for MY 2021/22.

Notes: (e) = estimate, (f) = forecast

Consumption

FAS/Canberra forecasts domestic canola crush to decrease to 1.0 MMT in MY 2023/24, from an upward revised estimate of 1.2 MMT in MY 2022/23. Crush volumes had been stable for several years at around 800,000 MT, as cooking oil consumption in Australia is fairly stagnant and merely increasing with population growth. But with another large canola harvest, albeit well below the record of MY 2022/23, the crush is expected to again be above past levels. With strong international canola oil prices, domestic crushers are forecast to be encouraged to produce at near capacity, but at a slightly lower level than the MY 2022/23 record canola production year.

Canola production in Western Australia and South Australia is almost entirely for exports, while canola from eastern Australia is typically destined for domestic crush with any surpluses sold on the export market. Western Australia only accounts for around 10 percent of Australia's total crush even though almost half of the national crop is produced there. This is in part due to the demand for the by-product, canola meal, being in greater need in the eastern states where the majority of the beef feedlots, dairy, swine, and poultry users are located.

A smaller crop for MY 2023/24, continued strong export demand for canola particularly from the biodiesel sector in the European Union (EU), and some industry analyst expectations that the current very high export canola oil prices are unlikely to be sustained in the forecast year, are all expected to dampen the demand for domestic crushing volumes from the peak in MY 2022/23.

MY 2022/23 canola consumption for crushing has been revised upwards by FAS/Canberra to 1.2 MMT, compared to the official USDA estimate of 900,000 MT. Australian canola oil export prices have been rapidly rising since 2020 to be near double in early 2023, which has encouraged processors to run at full capacity for MY 2022/23.

Trade

MY 2023/24 canola exports are forecast to be 4.5 MMT, a 1.8 MMT-decline from the estimate for MY 2022/23. This forecast decline is largely due to the anticipated lower canola production after the successive record smashing export results in MY 2021/22 (5.76 MMT) and estimated at 6.3 MMT for MY 2022/23. Despite the forecast decline in exports, if realized they would still be the third highest on record.

Australia is a significant world exporter of canola and surpassed Canada in MY 2021/22 to be the largest exporter (see Figure 8) due to lower production in Canada caused by drought and a big production year in Australia. However, Australia's position as the number one exporter is expected to be short lived despite a record estimate exports in MY 2022/23, due to much improved production in Canada and the expectation of a further decline in exports for Australia in the forecast year.

Figure 8 – World Canola Trade – Australia MY 2017/18 to 2021/22

Source: Trade Data Monitor

Note: Australia Marketing Year is December to November (eg MY 2021/22 = Dec 2021 to Nov 2022)

Over the last five years on average around 75 percent of Australia's exports have gone to the EU, primarily for the biodiesel market. However, trade with United Arab Emirates and Japan, and to a lesser degree the United Kingdom, has grown substantially since the rise in production, and subsequent exports, over the last two years (see Figure 9).

Figure 9 – Major Australian Canola Exports Destinations – MY 2017/18 to 2021/22

Source: Australian Bureau of Statistics

A major difference between Canadian and Australian supplies to the EU is that most of Canada's canola is GM, whereas most of what is exported to the EU by Australia is non-GM. Even though the primary use of Australian canola in the EU is for the biodiesel market, importer preference is for non-GM canola. This enables the meal by-product to be used in their livestock industries. However, if the premium for non-GM canola climbs too high, EU importers reportedly have some flexibility in sourcing GM canola to meet their demands. With increasing energy market prices and the primary purpose of exports to the EU being for biodiesel production, it is anticipated that the EU market will remain strong for Australia.

Canola exports in MY 2022/23 are estimated by FAS/Canberra to reach 6.3 MMT and marginally above the official USDA estimate (6.25 MMT). For the first two months of MY 2022/23 (December 2022 and January 2023) Australia has exported 1.5 MMT of canola, around 40 percent above the same time the previous year, setting a strong early pace towards the estimated record exports. However, a key issue for exporters is that the major canola exporting ports (see Figure 10) are the same ports that are handling Australia's record winter crop including much larger volumes of wheat and barley. Internal storage, transport logistics, and ports have risen to the challenge of tackling recent record winter crop production and is anticipated that ports will run at capacity throughout the year, but manage to cope with the estimated record winter crop export volume.

Stocks

FAS/Canberra forecasts ending stocks of canola to decline to around 594,000 MT in MY 2023/24 after a higher than usual level in the prior year after the record production. According to industry sources most of the canola is typically sold by the end of June each year and very little stock is held prior to the start of harvest at the beginning of November.

CANOLA MEAL

Production

Canola meal production is forecast to decline in MY 2023/24 to 580,000 MT from the upward revised estimate of 695,000 MT in MY 2022/23. The forecast is still equal to the second highest along with MY 2021/22. Canola meal production is driven by the crushing demand for canola oil, and also the strength of the canola meal by-product price typically has a bearing on the merits of crushing to produce canola oil. However, the current canola oil export price is exceptionally high for MY 2022/23, so the price of canola meal is of less importance in driving the current record crush estimate. However, the oil price is expected to taper off for MY 2023/24 which will contribute to the lower canola crush and meal production for the forecast year.

Canola meal is a high-quality protein rich supplement, high in rumen undegradable protein which is sought after in supplementary feeds for performance. It is used as an ingredient in a range of livestock industries, the largest of which is the beef cattle industry and behind this the dairy industry. High beef cattle prices and near record milk prices are encouraging higher use of supplementary feeds to increase productivity.

Canola production is forecast to decline by 34 percent in MY 2023/24, but canola meal production is forecast to fall by half that rate as typically less than one-fifth of Australian canola is crushed

domestically. MY 2022/23 canola meal production is estimated to be at capacity due to crushers taking advantage of the very strong canola oil export prices.

FAS/Canberra has upward revised the canola meal production estimate for MY 2022/23 to 695,000 MT, compared to the official USDA estimate of 518,000 MT. This large increase is driven by crushers processing at capacity in light of a record-busting canola crop and high world canola oil prices, and is estimated to achieve highest canola meal production on record.

Consumption

FAS/Canberra forecasts a slight increase in canola meal consumption in MY 2023/24 of 5,000MT to 580,000 MT from an upward revised 575,000 MT for MY 2022/23. As almost all canola meal produced in Australia is consumed domestically. Some of the big increase in canola crush in MY 2022/23 is expected to result in an increase in carry over stock into the forecast year enabling a continuation of the slow increasing canola meal consumption trend to continue into MY 2023/24.

Most of the canola meal is produced in crushing facilities in the eastern states that are near major users of meal including the pig, poultry and dairy industries. Canola meal competes to some degree with imports of soybean meal, which have been steadily increasing over the last two decades. Although soybean meal is the nearest direct competitor to canola meal, they do have differing characteristics and meet different livestock nutritional needs for ruminant and monogastric livestock industries. The import of soybean meal is almost entirely from Argentina.

Although Australia produces ample canola to increase its crush, there is not expected to be any expansion in crush capacity in the near to medium term in Australia. The demand for canola meal domestically is only steadily increasing from year to year (see Figure 11). This demand and associated price for the canola meal by-product is an important consideration in crush capacity utilization. The very high price of export canola oil over the last two marketing years has been enough to drive canola crushing margins without the need for significant canola meal price support, but this circumstance is not expected to continue in the short to medium term.

Figure 11 – Australian Canola Meal Consumption

Source: Australian Bureau of Statistics / FAS/Canberra

Trade

FAS/Canberra forecasts canola meal exports to remain stable in MY 2023/24 at 60,000 MT, in line with the upward revised MY 2022/23 estimate. This estimate is double that of the official USDA estimate after a big increase in trade for the first two months of the marketing year.

The first year of any significant canola meal exports was in MY 2021/22 at 27,000 MT, and the trade only began in the last five months of the marketing year. The trade is to China, New Zealand, and Vietnam for their livestock industries. With the likelihood of legislated changes in New Zealand for the purpose of greenhouse gas emissions reductions from agriculture, some analysts suggest that one pathway to reduced emissions is to increase the energy density of the feed which can be done via increased supplementary feeding. This may eventually drive a further increase in canola meal trade to New Zealand if their proposed legislation is passed into law.

FAS/Canberra has upward revised the canola meal export estimate for MY 2022/23 from the official USDA estimate of 30,000 MT to 60,000 MT. The first two months of exports for MY 2022/23 are at 11,000 MT. This is a similar pace from when the trade commenced in the final five months of MY 2021/22. With no change in the rate of exports for the remainder of MY 2022/23, the 60,000 MT estimate is expected to be achieved.

Stocks

Canola meal is a product that spoils and needs to be used within a matter of weeks. For this reason, ending stocks typically remain low and stable from year to year. However, dried canola meal can be

stored for many months, but it is unclear as to what industry capacity there is to produce dried canola meal.

CANOLA OIL

Production

With total canola crush forecast to decline in MY 2023/24, canola oil production is forecast to fall to 412,000 MT, 17 percent below the upward revised estimate of 495,000 MT in MY 2022/23. Crushers in MY 2022/23 have been encouraged to produce at capacity due to the very high canola oil export prices which escalated since late 2020. However, oilseed oil analysts and futures markets for canola oil indicate firm but softening prices in MY 2023/24, and along with a lower canola production forecast, this is expected to result in some easing in Australia's canola crush volume in the forecast year. Numerous reports from Canada indicate that their crushing industry has collectively announced plans to increase crushing capacity by around 6 MMT (over 50 percent) in the next two to three years. This increase in capacity is equivalent to around five times Australia's current crushing capacity. This anticipated big surge in Canadian canola oil crushing capacity is contributing to the sectors sentiment towards an easing of canola oil prices into the forecast year.

Australia has five canola crushing facilities in New South Wales and Victoria, the two most populated states with the greatest domestic demand for canola oil. There are a further two small crushing plants in Western Australia. Industry sources indicate that total combined crushing capacity is around 1.2 MMT.

MY 2022/23 canola oil production has been revised upwards by FAS/Canberra to 495,000 MT, compared to the official USDA estimate of 371,000 MT. This increase is partly driven by the bumper

crop, but also due to the very high canola oil export prices which increased 128 percent above the previous 5-year average since late 2020 (see Figure 12). This has encouraged crushers to produce at capacity for MY 2022/23 and drive increased export income. The rise in canola prices are associated with droughts in other major oilseed producing countries and the Russian invasion of Ukraine.

Figure 12 – Australian Canola Oil Export Price Trend

Source: Food and Agriculture Organization of the United Nations

Note: Time Period is from a larger data set from 1961-2021 and indexed to 100 in 2014-2016

Consumption

Canola oil consumption in MY 2023/24 is forecast to decrease moderately to 210,000 MT from the previous year's estimate of 220,000 MT. The lower canola production forecast for MY 2023/24, along with the anticipated softening of canola oil prices, is anticipated to result in a 17-percent decline in the canola crush reducing the available canola oil for domestic consumption and exports.

Biodiesel production from canola in Australia is practically non-existent, with no federal biodiesel mandate and only small mandates in two Australian states. Industry sources also indicate that it is more cost effective to produce biodiesel from tallow in Australia.

FAS/Canberra has upward revised the canola oil consumption estimate for MY 2022/23 from the official USDA estimate of 195,000 MT to 220,000 MT. This is mainly as a result of the 20-percent increase in estimated canola oil production in MY 2022/23 compared to the prior year. Australia uses many other oilseed oils most of which are imported (other than canola oil) and the large increase in world oilseed oil prices over the last two years is expected to result in some domestic users gravitating towards increased domestic supplies, which benefits from lower transport costs compared to imported products.

Trade

Australia's canola oil exports are forecast at 240,000 MT in MY 2023/24, a decline of eight percent from the upward revised estimate of 260,000 MT in MY 2022/23. With relatively stable domestic consumption, changes in canola oil production typically flow through to increased export volumes. As mentioned earlier, production of canola oil is forecast to decline partly due to the expectation of a smaller canola crop, but still remain high with the support of strong world canola oil prices (albeit likely to be softer than in MY 2022/23). China, New Zealand, Taiwan and South Korea have typically been largest markets for Australian canola oil exports, but over recent years Malaysia has also become a significant export destination.

FAS/Canberra revised the MY 2022/23 canola oil export estimate upwards to 260,000 MT, compared to the official USDA estimate of 190,000 MT. As mentioned earlier this is driven by crushers seeking to take advantage of the record busting canola production and very strong world oilseed oil prices.

Until MY 2017/18, palm oil was the second most consumed oil, and by far accounted for the largest percentage of cooking oil imports (see Figure 13). Since then, imports of palm oil have declined rapidly, and this trend was broadly expected to continue due to the increasing awareness of the environmental impacts that palm oil production has caused. However, the escalating cooking oil prices since late 2020 have resulted in importers partly reverting back to increasing imports palm oil, the lowest cost cooking oil. For a range of other cooking oils there has essentially been little change in imports. There have been small increases in palm kernel oil and soybean oil imports over recent years, but they are from very low levels.

Canola oil is by far the largest domestically produced cooking oil in Australia. The longer-term decline in cooking oil imports has only in small part been met by increasing canola oil production. With typically less than 20 percent of canola production in Australia being crushed there is ample opportunity for further increases in canola oil production in Australia. However, unlike in Canada, there have been no indications of any intent from canola crushing facilities in Australia to expand their production capacity.

The import forecast for MY 2022/23 is for 15,000 MT, the same as the estimate for MY 2022/23. This represents four percent or less of canola oil production in Australia and is equivalent to only around six percent of the export volume. Canola oil imports for the first two months of MY 2022/23 (December 2022 to January 2023) are slightly lower than for the same period in the previous year. With a bumper canola harvest and crushing running at capacity in MY 2022/23 it is unlikely that canola oil imports will be any greater than 15,000 MT.

Figure 13 – Australian Cooking Oil Import Trend – MY April to January

Source: Australian Bureau of Statistics

Stocks

Canola oil ending stocks are typically consistent from year to year, but stocks in MY 2023/24 are expected to decline - towards more typical levels - after an increase in MY 2022/23 associated with the Australian canola crushing sector boosting production to capacity.

OLIVE OIL

Production

Australian olive oil production is forecast to decrease to 20,000 MT in MY 2023/2024, a 13-percent decline from the FAS/Canberra MY 2022/23 estimate of 23,000 MT. The primary reason for the forecast decrease is accounting for the natural biennial effect of olive fruit yields declining following an up year. The scale of the decrease is far less pronounced than the previous down year in MY 2021/22, partly due to more new olive trees coming into production, and others increasing yields as they mature.

The Australian olive oil industry typically produces 90 to 95 percent Extra Virgin Olive Oil (EVOO) which is processed via a cold press technique and is known as a premium product. Further olive oil can be extracted from the post cold pressed olives via chemical extraction methods and is sold as olive oil or used in other products. The chemically extracted olive oil is a lower quality and lower value product.

Industry sources report that in Australia the EVOO average annual extraction rate typically ranges from 15 to 18 percent. Lower extraction outcomes are largely due to higher moisture content fruit from poorer seasonal conditions, but also driven by some producers commencing harvest prior to optimal oil content for logistics purposes and also smaller producers with less-than optimal extraction equipment.

Many of the large producers have removed earlier planted groves with varieties which have since proven not to perform to adequate levels and have replanted these areas with proven varieties, and some are continuing to finalize these programs. There are also substantial expanded tree plantings, with estimates of up to 40 percent of trees being less than five years old and which do not bear any olives or have very low production. Typically, olive trees gradually increase production between year six and 14 after which they reach mature production levels. These larger producers are estimated to have 30 percent of their trees in the year six to 14 profile and 30 percent of trees at maturity. Mature trees of these large producers achieve approximately 15 MT/ha of harvested olives based on traditional tree spacing. Small areas of high-density hedge plantings are reported to achieve well in excess of 20 MT/ha.

As the number of olive trees in Australia increasingly progress towards mature production the expectation is that the industry will achieve relatively consistent year on year production growth over the next 15 years. Larger producers have reported plans for substantial increases in plantings over the next five years primarily in the most optimal temperate growing regions of southern New South Wales, northern Victoria, and the south-west corner of Western Australia.

Industry sources report that the seasonal conditions for the MY 2022/23 crop to be harvested from mid-March to July 2023 have been favorable. Above-average rainfalls and mild conditions in the lead up to flowering and fruit set are reported to have produced very good fruit set results. Since the fruit set period, seasonal conditions have generally remained mild with a cooler than usual summer period which has resulted in the crop development running a little later than is typical. Overall, the industry reports that fruit yield and quality appear promising in the lead up to the start of harvest. Industry sources

estimate olive production of up to 130,000 MT and expect oil extraction rates to be at the higher end of the normal range. This equates to olive oil production of around 23,000 MT for MY 2022/23 resulting in the FAS/Canberra estimate slightly lower than the official USDA estimate of 24,000 MT.

FAS/Canberra has also downward revised the MY 2021/22 production to 15,000 MT. The Australian olive industry indicates that olive fruit production was a little lower than estimated at the start of harvest last year and extraction rates were relatively low as had been expected at the time. On this basis production has been downward revised to 15,000 MT from the official USDA estimate of 20,000 MT.

Consumption

FAS/Canberra forecasts consumption of olive oil in Australia at 55,000 MT in MY 2023/24, in line with the MY 2022/23 estimate.

In Australia, EVOO is not perceived as a cooking oil and is not considered interchangeable with canola and vegetable oils for cooking. The majority of Australian EVOO is expected to continue to be sold through domestic retail outlets. On this basis consumers are not expected to make significant preference shifts between cooking oils and extra virgin olive oils from year to year.

FAS/Canberra has revised the consumption estimate for MY 2022/23 from the official USDA estimate of 65,000 MT to 55,000 MT. Similarly, the result for MY 2021/22 has been revised down from 60,000 MT to 50,000 MT.

Trade

FAS/Canberra forecasts Australian imports of olive oil to remain flat at 35,000 MT for MY 2023/24. Imports do not tend to change significantly with changes to domestic production associated with the biennial affect from year to year. Major domestic suppliers plan and account for this to ensure consistent supply to the market from year to year by building up stock in the up years and drawing down on stocks in the down years.

Industry sources indicate that of the olive oil imported, approximately 40 percent is sold via the retail network of which a proportion is EVOO and the balance lower-quality olive oil. Approximately 60 percent of imported olive oil is sold to the food industry sector and predominantly lower quality oil.

Spain is by far the major supplier of olive oil to Australia at around three quarters of overall supply followed by Italy and Greece (see Figure 14). These three countries have consistently supplied around 95 percent of overall imports to Australia for over the last 20 years.

Figure 14 – Australian Olive Oil Imports

Source: Australian Bureau of Statistics

Note: Australia Marketing Year is January to December (eg MY 2020/21 = Jan 2021 to Dec 2021)

FAS/Canberra has downward revised the import estimate for MY 2022/23 to 35,000 MT from the official USDA estimate of 45,000 MT. Similarly, the result for MY 2021/22 has been revised down from 42,000 MT to the actual trade result of 34,000 MT. Imports do not vary greatly from year to year despite the variance in domestic production caused by the biennial production affect. Instead, as mentioned earlier domestic suppliers store greater amounts of olive oil after a high production year to ensure adequate supply after a low production year to consistently meet their domestic supply commitments.

FAS/Canberra forecasts export of Australian olive oil in MY 2023/24 at 2,000 MT, in-line with the prior year estimate. Australia is expected to remain a net importer of olive oil in the foreseeable future, although export volumes are expected to increase in the coming years after existing olive groves mature and a sustainable overall increase in production is achieved.

Stocks

Ending stocks are forecast at 10,000 MT in MY 2023/24, down 2,000 MT from the MY 2022/23 estimate of 12,000 MT. Stocks are expected to step down in what is forecast to be a lower production year.

COTTONSEED

Production

FAS/Canberra forecasts cottonseed production to rise to 1.52 MMT in MY 2023/24, from estimated production of 1.44 MMT in MY 2022/23. If realized, the forecast production would be the third highest on record from the peak of 1.68 MMT in MY 2010/11 and the second highest result of 1.53 MMT in MY 2021/22. The forecast production is mainly based on the anticipation of a return to normal seasonal conditions at planting and the strong likelihood of ample irrigation water availability.

The five-percent increase in forecast production for MY 2023/24 is primarily due to an expected improvement in average yield. In part the improvement in yield for the forecast year is due to an anticipated expansion in irrigated cotton planted area and a decrease in planted area of lower yielding dryland cotton. Also, with the assumption of more normal conditions at planting for the forecast crop it is anticipated that planting will occur in a timely and more optimal period compared to the highly disrupted and extended planting period for the MY 2022/23 crop. Further to this, there is a high degree of confidence that there will be ample irrigation water availability for producers to support an expanded irrigated cotton planting.

Although almost 90 percent of cotton production is from irrigated areas, the forecast rise in cotton production for MY 2023/24 is unrelated to any change in irrigation water availability. There was more than ample irrigation water available for the MY 2022/23 crop but excessive rains in spring 2022 markedly disrupted planting, the severity of which was abnormal. It is considered highly unlikely that there would be two successive years of such major planting disruption, so the forecast is based on typical conditions at planting.

The bumper MY 2021/22 crop was a result of a major improvement in irrigation water availability, and this has continued in MY 2022/23 and is expected to extend into the forecast MY 2023/34 season. This is a reflection of the three successive years of well-above-average rainfall in the major cotton producing regions from 2020 to 2022. This has occurred only on two other previous occasions (1973-1976 and 1998-2000) in recorded history. For the second successive year, the irrigation water storages affecting the major cotton producing regions are near capacity at the beginning of March, which is the tail end of the irrigation season (see Figure 15). Even in the event that below average rainfall in the irrigation water catchments in the winter spring period of 2023 were to occur, there is a strong likelihood that storage levels will remain high and offer cotton producers the confidence that they will have ample irrigation water available for the MY 2023/34 crop.

Figure 15 – Irrigation Storage Levels - Early March 2022 and 2023

Source: Murray Darling Basin Commission

The Australian cotton industry has a mix of both dryland and irrigated cropping. However, both are typically located in the same growing regions as the water holding capacity of soils and the climatic conditions are well suited to cotton production there. Irrigated cotton yields are typically 2-3 times higher than that of dryland cotton. Irrigated cotton areas are thus by far the primary driver of overall cotton production in Australia, and this in turn is driven by irrigation water availability.

Irrigation water is derived from a combination of sources, one of which is water harvested and stored in on-farm dams from overland flows. This can occur after high rainfall events more typical in the more northern cotton production regions. Water is also harvested and stored from waterways during high flow periods also after high rainfall events which occurs across the northern and central cotton production regions. Underground water is also a source of irrigation water although relatively small compared to the combination of other sources. The main source of irrigation water, that has a large bearing on cotton plantings, is multiple irrigation schemes based on large storage dams. The southern cotton production region is almost entirely dependent upon these dams whereas the central region and most northern regions have a high dependence on them.

FAS/Canberra's cottonseed production estimate for MY 2022/23, with harvest just about to commence in April 2023, is downward revised to 1.44 MMT, 13 percent below the official USDA estimate of 1.65 MMT. The large downward revision is due to the very wet conditions at planting and also the cooler-than-usual temperatures through to the end of December 2022, which restricted the cotton crop development.

Despite anticipation of a near record cottonseed production for MY 2022/23, the planting period in spring 2022 was severely hampered by multiple flooding events, from near-record to record rains (see Figure 16), particularly through the major New South Wales cotton producing areas. Planting was not only stretched into a "far from optimal" late spring period, but some were unable to plant their full intended cotton program, particularly so for those in the more southern areas of New South Wales. Further adding to this issue was that the spring and early summer periods were cooler than normal resulting in the crop development being well behind typical expectations. However, the January and February periods have been warmer, and the crop development has partially caught up, but harvest is still expected to start around two weeks later than normal. With the late planting and challenging early growing conditions, yields are anticipated to be well below average. Nevertheless, despite the challenging conditions during planting and the early growth period there was still a big planted area, and overall production of cottonseed will be very large with expectations that it will be the third largest ever result for Australia.

Figure 16 – NSW Rainfall – October to November 2022

Source: Australian Bureau of Meteorology

Consumption

FAS/Canberra forecasts total domestic cottonseed consumption to increase to around 900,000 MT in MY 2023/24 from the prior year estimate of 820,000 MT. Much of this is anticipated for domestic livestock feed use but the increase is due to the anticipated expanded cottonseed crush. Dehulled product is planned to be transported to a crushing facility on the east coast of New South Wales which is focused on canola seed crushing. At this point the expected crushing volume of cottonseed in this facility is unclear, but on the basis that the product will be crushed in a canola crushing plant, it is anticipated that the volume of cottonseed crushing will be relatively small.

Cottonseed is a high-quality feed supplement primarily used in the livestock cattle industries and can be fed whole without any processing. It is a sought-after product for its high protein and oil content. It is typically used as part of a feed ration in beef feedlots but is also used by beef producers in the dairy industry in a partial mixed ration with other gains and fiber sources as a supplement to pastures.

The cotton industry in Australia has only one major crushing facility based in Narrabri in New South Wales which has been mothballed over recent years due to a lack of cottonseed supply associated with the previous drought. There are indications that the facility would recommence operations in May 2024 but would only be dehulling the cottonseed. The product would then be transported to a canola crushing facility in the east coast of New South Wales for crushing. On the basis that canola crushing facilities more broadly are anticipated to be operating at near capacity in MY 2023/24 it is not anticipated that there will be a large increase in cottonseed crushed in the forecast year. There is one other small

crushing plant focused on supplying by-products to an associated livestock feed processing mill rather than for cottonseed oil production. Their crush demand of around 20,000 MT is unlikely to change significantly even with a large increase in cottonseed supply.

FAS/Canberra has revised down the cottonseed consumption estimate for MY 2022/23 from the official USDA estimate of 955,000 MT to 820,000 MT. This revised estimate is already at the high end of the livestock industry consumption capacity, particularly considering that there is no major drought in the livestock grazing industries, and canola crushing is running at capacity producing higher volumes of canola meal which is also extensively used in livestock rations.

Trade

FAS/Canberra cottonseed exports are forecast to remain stable to 600,000 MT in MY 2023/24. Although there is an expectation of a five-percent increase in cottonseed production in the forecast year, much of this increase is likely to go towards increased cottonseed crush.

FAS/Canberra has revised the cottonseed export estimate for MY 2022/23 to 600,000 MT, still the largest since MY 2011/12, from the official USDA estimate of 700,000 MT. The downward revision is mainly due to the reduced cottonseed production estimate. Australia has in the past exported similar quantities almost all to China, South Korea, Japan and United States (see Figure 17) but only averaging a little over 250,000 MT over the last 10-years. With two months remaining in MY 2021/22, Australia has exported 644,000 MT of cottonseed and is on track to reach 650,000 MT which will be the second highest result on record. These exports are going to the same four markets, and it is clear that trading relationships have been maintained despite the low export volumes over the previous nine years. The previous record export result of 783,000 MT was achieved in MY 2011/12.

Figure 17 – Cottonseed Export Destinations - Apr to Jan MY 2011/12 to 2022/23

Source: Australian Bureau of Statistics Note: (e) = estimate, (f) = forecast

Stocks

FAS/Canberra forecasts a modest increase in cottonseed ending stocks in MY 2023/24 after three successive years of anticipated large cottonseed production. Stocks cannot build up to high levels as there are limited cottonseed storage facilities and it is more challenging to store than the likes of cereal grains. This creates a greater imperative to offer cottonseed at a price that attracts buyers before the product spoils and goes to waste.

COTTONSEED MEAL

Production

FAS/Canberra forecasts cottonseed meal production to increase to 48,000 MT in MY 2023/24 from an estimated 9,000 MT in MY 2022/23. This substantial increase as mentioned earlier relates to the expected re-establishment of increased cottonseed processing capacity.

FAS/Canberra's MY 2022/23 cotton meal production estimate remains at 9,000 MT, three times higher than the official USDA estimate of 3,000 MT. This relates to the volume of cottonseed processed at a facility in the Riverina region of New South Wales which produces cottonseed meal cake as an ingredient for an associated livestock pellet feed production facility.

Consumption

FAS/Canberra forecasts total cottonseed meal consumption to increase to 38,000 MT in MY 2023/24 from 9,000 MT estimated for MY 2022/23. This is largely associated with the increase in crushing capacity in the forecast year as previously mentioned. All domestically consumed cottonseed meal is used in the livestock industries. Australia previously had much higher cottonseed crushing capacity and from MY 2010/11 to MY 2017/18 had consumed from 250,000 MT to 350,000 MT per annum in the

livestock industries. On this basis, the relatively small increase in forecast consumption will readily be absorbed by Australia’s livestock industries, particularly considering that canola meal production is expected to decline by 115,000 MT in the forecast year.

Similar to production, and for the same reason, FAS/Canberra has a cottonseed meal consumption estimate of 9,000 MT compared to the official USDA estimate of 3,000 MT for MY 2022/23.

Trade

FAS/Canberra forecasts cottonseed meal exports to increase to 10,000 MT in MY 2023/24 from no exports estimated for MY 2022/23. This is, as previously mentioned, associated with the anticipated increase in cottonseed crushing in the forecast year.

Cottonseed meal exports over the last 10 years have been as much as almost four-fold higher than that forecast for MY 2023/24 (see Figure 18). Similar to the circumstance for cottonseed exports, Australia is likely to be able to re-establish trade with past major export destinations for cottonseed meal which has primarily been to New Zealand and South Korea.

Figure 18 – Cottonseed Meal Export Destinations - Apr to Jan MY 2011/12 to 2023/24

Source: Australian Bureau of Statistics
Note: (e) = estimate, (f) = forecast

Stocks

Due to the short shelf life of wet cottonseed meal no stocks are carried over from year to year.

COTTONSEED OIL

Production

FAS/Canberra forecasts cottonseed oil production to increase to 17,000 MT in MY 2023/24. As mentioned earlier this relates to the anticipated increase in cottonseed crushing for the forecast year.

FAS/Canberra's MY 2022/23 cottonseed oil production estimate remains at 3,000 MT, and is 1,000 MT higher than the official USDA estimate of 2,000 MT. As previously mentioned, this relates to the volume of cottonseed processed at the sole cottonseed crushing facility in Australia that produces cottonseed meal cake for inclusion into the production of livestock pellet feed. The cottonseed oil produced from this facility is sold into the domestic market.

Consumption

FAS/Canberra forecasts total cottonseed oil consumption to remain relatively stable at 35,000 MT in MY 2023/24. With an anticipated increase in production, cottonseed oil imports are expected to decline, and exports recommence for the first time in many years to accommodate the higher production with little change to domestic consumption.

After the major cottonseed crushing plant was mothballed in late 2018, imports of cottonseed oil increased somewhat but by nowhere near enough to maintain past consumption levels. Consumption levels reached over 120,000 MT over the last 10 years but have plummeted to around a quarter of that level since domestic production all but ceased (see Figure 19). Users of cooking oil in Australia had adjusted to sourcing alternate products, and without a far more significant increase in cottonseed oil production than that forecast, it is unlikely that there will be any significant change to cottonseed oil consumption.

Figure 19 – Australian Cottonseed Oil Consumption History

Source: PSD Online / FAS/Canberra

Note: (e) = estimate

Note: Australia Marketing Year is April to March (eg MY 2020/21 = Apr 2021 to Mar 2022)

FAS/Canberra has slightly revised down the estimated domestic consumption for MY 2022/23 to 33,000 MT from the official USDA estimate of 35,000 MT. With almost no domestic production of cottonseed oil anticipated in the estimate year to trigger any shift in the use of various cooking oils, consumption of cottonseed oil is not expected to change substantially from the prior year.

Trade

FAS/Canberra forecasts cottonseed oil imports to decline by 17 percent to 25,000 MT in MY 2023/24 from the prior year estimate. This is due to the anticipated increase in domestic production of cottonseed oil, much of which is expected to be sold into the domestic market which is expected to lower Australia's import volume requirements.

Over recent years while Australia has produced very little cottonseed oil, over 99 percent of overall imports have been from Argentina, Malaysia, Turkey, Brazil, and the United States (see Figure 20).

FAS/Canberra has moderately revised down the estimated import of cottonseed oil to 30,000 MT for MY 2022/23 from the official USDA estimate of 33,000 MT. The FAS/Canberra estimate is slightly above the final expected volume of imports for MY 2021/22.

With the forecast of a significant increase in cottonseed oil production for MY 2023/24 FAS/Canberra forecasts that exports will be at 5,000 MT from zero exports in the previous decade. This is in part due to domestic wholesalers taking time to adjust to the increase in domestic production but also establish some comfort that there will be a degree of reliability to the domestic supply. As a consequence, there may be a need to export some of the domestically produced cottonseed oil.

Figure 20 – Major Cottonseed Oil Imports – Apr to Jan MY 2019/20 to 2020/21
