Date: April 06, 2026

Report Number: UK2026-0006

Report Name: Oilseeds and Products Annual

Country: United Kingdom

Post: London

Report Category: Oilseeds and Products

Prepared By: Jonathan Little

Approved By: Anita Katial

Report Highlights:

In Marketing Year (MY) 2026/27, UK rapeseed plantings are forecast to increase by 27 percent compared to the previous year's 42-year low, driven by improved market prices, better pest management strategies, and policy changes affecting agri-environment schemes. Production is forecast to exceed 1 million MT for the first time since 2023, with crushing volumes expected to reach 1.75 million MT, and import requirements for both rapeseed and rapeseed meal significantly reduced. U.S. soybean meal exports to the UK are experiencing strong growth, up 24 percent in the first four months of MY 2025/26, driven by UK retailers' voluntary commitments to deforestation-free soy and the continued wait to implement the UK Forest Risk Commodities legislation.

Disclaimer: This report presents Post’s first outlook for oilseeds and products, and Production, Supply and Distribution (PSD) forecasts for the Marketing Year (MY) 2026/27, as well as estimates for MY 2025/26 and the historical context of MY 2024/25. Unless stated otherwise, data in this report is based on the views of Foreign Agricultural Service analysts in the UK and is not official USDA data. USDA official numbers in this report include the World Agricultural Supply and Demand Estimates (WASDE) March 2026 release.

Trade figures are revised according to the most recent data available from Trade Data Monitor (January 2026).

Abbreviations used in this report:

EU	European Union
FAS	Foreign Agricultural Service

The marketing years used in this report are:

January - December

Palm kernel meal / oil

Palm oil

July - June

Rapeseed complex

October - September

Soybean complex

Sunflower complex

Peanuts

Executive Summary

In Marketing Year (MY) 2026/27, the United Kingdom's oilseeds sector shows signs of recovery, particularly for rapeseed production. Plantings are forecast to increase by 27 percent compared to the historically low base of MY 2025/26, which saw the lowest area planted in 42 years. This improvement is driven by higher market prices relative to other crops, better agronomic strategies to combat Cabbage Stem Flea Beetle damage, and policy changes including the closure of England's main agri-environment scheme to new entrants. Production is forecast to exceed 1 million MT for the first time since 2023, with yields expected to reach over 3.5 MT/Ha. Crushing volumes are anticipated to increase to 1.75 million MT, capitalizing on improved domestic supply and better crush margins.

The UK's trade position in rapeseed continues to reflect its deficit status following the neonicotinoid ban, though higher domestic rapeseed production in MY 2026/27 is forecast to reduce import demand by approximately 120,000 MT. The origin of imports has shifted significantly, with EU suppliers displacing Ukraine following the implementation of export duties in September 2025. For soybeans, the UK remains entirely dependent on imports, with Brazil supplying the primary crush facility from March to October and North American sources filling the gap from November to February. Notably, U.S. soybean meal exports to the UK are experiencing strong growth, up 24 percent in the first four months of MY 2025/26, driven by UK retailers' voluntary commitments to deforestation-free soy and the continued wait to implement the UK Forest Risk Commodities legislation. This trend is expected to continue in the short term as the UK animal feed sector seeks verifiably low deforestation-risk protein sources.

Consumption patterns reflect the UK's livestock sector dynamics, with rapeseed meal extensively used in dairy feed rations and soybean meal remaining the preferred choice for poultry and swine production. Feed consumption in MY 2026/27 is forecast to increase modestly for rapeseed, soybean and sunflower meal, supported by continued growth in poultry numbers offsetting reductions in cattle. However, a reduction in imports of palm kernel meal, due to the abundance of other meals, is forecast to leave overall feed consumption broadly flat year-on-year, with other cheaper feedstuffs more plentiful.

Rapeseed oil demand for food use remains strong and is expected to grow slightly, partly due to consumer shifts away from palm oil perceived as being less sustainable. Industrial use of vegetable oils remains constrained by the UK government's Renewable Transport Fuel Obligation, which caps crop-based biofuel contributions on a declining trajectory to two percent by 2032.

Policy developments continue to shape the sector's outlook. The abrupt closure of the Sustainable Farming Incentive scheme to new entrants in March 2025 and subsequent payment rate reductions may release additional land for rapeseed cultivation in MY 2027/28. The UK has diverged from the EU in the area of biotechnology approvals, with the Precision Breeding Act offering potential for innovation in crop resilience. Meanwhile, the UK's post-Brexit Genetic Engineering approval process has created a growing backlog compared to the EU, potentially impeding imports, though this could be resolved following implementation of the proposed UK-EU Sanitary and Phytosanitary agreement. The industry's 'Reboot Campaign' has successfully disseminated agronomic strategies to combat pest damage, contributing to improved grower sentiment in the rapeseed crop and the beginning of a recovery in planted area after years of decline.

Rapeseed – Oilseed

Production

In MY 2026/27, plantings of rapeseed oilseed (rapeseed) are forecast to increase by 27 percent compared to the low base of the previous year (MY 2025/26), which saw the lowest area planted in the United Kingdom (UK) for 42 years. The relative improvement in grower sentiment behind this increase has been driven by a number of factors, including higher market prices compared to other combinable crops, and a perception that a practical toolkit of agronomic strategies can help reduce crop damage from Cabbage Stem Flea Beetle (CSFB), the pest that has dented confidence since neonicotinoid insecticides were banned in 2018. Policy changes may have also contributed to this increase in plantings following the closure to new entrants of the main entry-level agri-environment scheme in England in March 2025 (as described in the Policy section below). While plantings for MY 2026/27 are back above 300,000 Ha, putting this in a historic context, this is still well below the area grown in 2023 and almost all the previous years in the recent past.

Latest crop development reporting for MY 2026/27 from the Agriculture and Horticulture Development Board suggests only a small proportion of the planted area will struggle to make it through to harvest. Indeed, at the time of writing, these reports indicate the prospects look optimistic, with 84 percent of the crop rated good to excellent, up from 57 percent this time last year and just 31 percent in March 2024. While winter 2025/26 has been exceptionally wet in England, with around 35 percent more rainfall than the long-term average, it does not seem to have had a significantly negative impact on crop growth, with little evidence of loss through waterlogging. The forecast yield for MY 2026/27 is therefore up on the five-year average, at over 3.5 MT/Ha, although with more clement weather facilitating timely operations and minimal crop damage from pigeons and CSFB, the yield could ultimately rival or even surpass the 3.7 MT/Ha from MY 2025/26. Production for MY 2026/27 is forecast to be back over 1 million MT, the first time this threshold will be surpassed since the 2023 harvest.

Consumption

The UK primarily utilizes rapeseed for crush byproducts, specifically rapeseed meal and rapeseed oil. Rapeseed oil is a high-end product for use as a consumer ready frying/cooking oil and the most important usage for rapeseed in the UK.

Domestic demand comes from three UK oilseed crushers – ADM in Erith, Cargill in Liverpool, and a newer operator, Yelo, near Stratford-upon-Avon. Rapeseed is also used directly by animal feed compounders.

In MY 2026/27, crushing volumes are expected to increase to 1.75 million MT, capitalizing on the increased availability of domestically grown rapeseed and the associated higher crush margins. This forecast crush volume is up on the total for MY 2025/26, which is expected to have been impacted by a temporary, technical issue in one of the three commercial crushing plants in the UK.

Trade

Reduced domestic production following the ban on neonicotinoid insecticides flipped the UK from being a traditional exporter of rapeseed into a deficit market. However, higher domestic production in MY 2026/27 is forecast to reduce the demand for imports by around 120,000 MT compared to the previous year, which itself is a volume that is estimated to be significantly down (in MY 2025/26) due to the technical issue affecting one of the UK crush plants mentioned above.

Figure 1: Main Rapeseed Supplies in the UK (in MT)

Source: TDM & Defra

The origin of import supplies has changed markedly in MY 2025/26, with Ukraine's market share halving following the implementation of Ukraine's export duty policy in September 2025. Imports from the European Union (EU) have largely displaced the supplies that had been arriving from Ukraine in the last couple of years, with 155,000 MT coming from Romania between July 2025 and January 2026. Exceptionally, 40,000 MT of U.S. origin rapeseed also arrived in the UK in August 2025, a trade flow that had not been seen previously. EU supplies are anticipated to retain their dominant market share in MY 2026/27.

Exports of rapeseed oilseed from the UK mainly go to the Netherlands, Belgium, Sweden and Germany, largely for specialist/industrial uses (i.e. High Erucic Acid Rape).

Figure 2: Main Rapeseed Exporters to the UK (in MT)

Source: TDM (with ‘Unidentified’ included with EU origin)

Stocks

For MY 2025/26 and MY 2026/27, stocks are forecast to remain steady around 85,000 MT, roughly the minimum needed to provide security of supply to the domestic crushing plants.

Rapeseed meal

Production

Production of rapeseed meal is forecast to be back up to almost 1 million MT in MY 2026/27, with locally derived supplies of domestic and EU rapeseed readily available. A better balance in MY 2026/27 between domestically grown rapeseed and imports is also likely to improve crush margins as well as logistics for the UK’s largest crush plant located on the Thames Estuary which was not designed to be so reliant on imported seed as it has been in recent years.

Figure 3 below shows the EU’s export dominance in supplying the UK rapeseed meal market. In the seven months to January 2026, Canadian exports have though occupied a 39 percent share, during a period when Canadian rapeseed exporters have sought alternative markets following the imposition of Chinese tariffs in March 2025.

The forecast for imports of meal in MY 2026/27 is down 9 percent on the previous year, reflecting the higher anticipated domestic crush and the resolution of the technical issue referred to above.

Figure 3: Main Rapeseed Meal Exporters to the UK (in MT)

Source: TDM (with ‘Unidentified’ included with EU origin)

Feed Consumption

The UK livestock sector is the primary demand driver for rapeseed meal, with it used extensively in dairy feed rations. For MY 2026/27, the continued increase in both pig and chicken numbers is forecast

to offset a reduction in head of cattle to leave the forecast of feed consumption slightly up on the previous year.

Rapeseed meal can be substituted with soybeans and soybean meal, domestic sunflower meal, and other grains in feed formulations, depending on global prices. In dairy production, rapeseed meal has become the dominant feed ingredient as an affordable alternative to soybean meal. For poultry and swine production, soybean meal remains the top choice in feed ratios. In MY 2025/26, a higher proportion of rapeseed meal is reported as being included in cake and compound feed, at the expense of some soyabean and sunflower meal. This increase in rapeseed meal is despite the increased affordability of cereals.

Ending stocks for MY 2026/27 are forecast to be stable, providing roughly one month's supply of feed consumption.

Rapeseed Oil

Production

The UK predominately produces oil for food use with a small, but stable, quantity for industrial use. In MY 2026/27, higher crush volumes will result in increased rapeseed oil production, principally due to the higher availability of domestically produced rapeseed. Imports of rapeseed oil in MY 2026/27 are forecast to reduce correspondingly.

Consumption

Demand for rapeseed oil for food use remains high and is forecast to grow slightly in MY 2026/27, in part due to a shift away from alternatives, like palm oil, perceived as less sustainable options. Between July 2025 and January 2026, more than 90 percent of imports had come from the Netherlands, Germany, Belgium and France, with the EU accounting for almost all the trade supply.

Industrial consumption remains a small but stable part of UK consumption. UK biofuel production is constrained by the commitment in the UK government's [Renewable Transport Fuel Obligation](#), which has set a cap on the crop-based contribution of biofuels, with that maximum level decreasing on a linear path from four percent initially down to two percent by 2032. In 2026, the crop cap has reached its statutory target level of 3.00 percent, the midpoint in its incremental decrease, which started in 2018. This is a subset of an increasing biofuel obligation, which may offset the decreasing proportion of crop-based biofuels.

Soybean Seed

Consumption and Trade

While plant breeding efforts are being devoted to producing varieties better suited to northerly climates, negligible quantities of soybeans are currently grown in the UK. The soybeans imported into the UK are predominantly used for crushing, food use, and livestock feed.

The primary UK crush facility, located in North-West England, completed a major upgrade five years ago, making it one of the most efficient plants in Europe. Throughput is consequently higher, and gradually improving, with a crush volume of just under 1 million MT of soyabean forecast for MY 2026/27, slightly up on the estimate for MY 2025/26. For MY 2024/25, industry contacts confirm that the New Post figure for crush volume is more accurate, with total domestic consumption amended accordingly.

Imports are largely a function of crush demand, with less than a tenth of the overall market for soybean seeds devoted to a combination of animal feed and human food use. This former category of beans, imported in lorries rather than Panamax ships, is forecast to decrease in MY 2026/27, based on information gathered from industry contacts.

The largest supplier of soybeans is Brazil, feeding the sole industrial-scale UK crush facility between March and October. Imports from the United States and Canada supply the same plant between November and February, with a shipment of 66,000 MT of Uruguayan soybeans also coming in during MY 2024/25.

Figure 4: Main Soybean Seed Exporters to the UK (in MT)

Source: TDM (with ‘Unidentified’ included with EU origin)

For MY 2026/27, Post forecasts that the United States may provide a larger share of North American origin supplies, with an anticipated extra shipment (of 65,000 MT) compared to MY 2025/26, up to a total of 275,000 MT.

The ‘just-in-time’ nature of the crushing operation normally means that soybean storage in the UK is limited to around two weeks’ of crushing volume. However, unusual circumstances at the end of MY 2024/25 – involving the docking of a shipment at the end of September 2025, combined with 50,000 MT in store due to an earlier downtime for the crushing plant – led to anomalously high carry-over stocks into MY 2025/26.

Soybean imports’ competitiveness with rapeseed in the livestock feed sector depends on input costs and protein content. The growth in UK poultry numbers in MY2026/27 favors demand for soy relative to other feedstuffs.

Soybean Meal

Consumption and Trade

In MY 2026/27, overall imports of soyabean meal are forecast at 2.4 million MT, slightly down on previous years, with this partly offset by a slight increase in domestic production. Argentina remains the key exporter to the UK market, taking half of the market share in MY 2024/25 with over 1.2 million MT of soyabean meal, due to its price competitiveness and high protein content. Brazil regained its traditional second largest share (at 18 per cent) largely because the rest of the market was fragmented between other suppliers such as Paraguay, the EU and the United States.

Figure 5: Main Soybean Meal Exporters to the UK (in MT)

Source: TDM (with ‘Unidentified’ included with EU origin)

In the first four months of MY 2025/26, U.S. exports are up 24 percent compared to the same period the previous year, underpinning Post’s estimate that the full-year trade will reach 200,000 MT. Soy traders confirm this upward trend is driven by UK retailers’ voluntary commitments to deforestation-free soy in food and feed, with this expected to boost demand for North American origin soybean meal in the next two years. Comparing the three-year average between 2022/23–2024/25 against 2019/20–2021/22 U.S. imports of soymeal are already up 235 percent, with cosignatories of the UK Soy Manifesto and UK Retail Soy Group all working towards supply chains using exclusively deforestation-free soy. While the UK’s Forest Risk Commodities legislation is still pending, demand has surged for North American soybean meal in UK animal feed rations as a proxy for a verifiably low deforestation-risk supply.

In terms of overall demand in MY 2026/27, the modest increase forecast in domestic feed consumption is based on a slight rise in poultry numbers, with fluctuations in pig and cattle numbers largely offsetting each other. This means that the higher supplies forecast for MY 2026/27 and 2025/26 are expected to be absorbed by this extra feed consumption.

Soybean Oil

Consumption and Trade

UK soybean oil imports and food use remain strong while industrial use remains around 25,000 MT per year. Any fluctuation in domestic soybean crush is met by imports of soybean oil, almost entirely from the EU providing the readily available supply of non-genetically engineered soybean oil demanded by UK retailers.

Note: As highlighted in previous reports, a suspected anomaly with the classification of peanut ‘seed’ imports from the United States in the trade data that created a deviation between the Post data and USDA Official numbers now seems to have been resolved, with ‘peanut seed’ imports back down to zero.

Policy

As set out in our last UK [Oilseeds and Products Annual report](#), there have been only a small number of policy areas where the UK has sought to utilize its Post-Brexit freedoms to deviate from the EU. Of relevance to the oilseeds market, the UK has adopted a streamlined approach to biotechnology application renewals and a markedly different position on domestic agricultural support in England, prioritizing funding for agri-environment measures in the form of its Environmental Land Management schemes. In relation to trade policy, the voluntary tariff suspension on sunflower-seed oil introduced at the start of 2023 due to supply chain disruptions caused by the war in Ukraine has been extended until the end of December 2026, with active consideration given to extending it further to the end of December 2028. (More information can be found in the GAIN report entitled '[UK Tariff Suspensions December 2025 update](#)'.)

Biotech Policy and Approvals

Following Brexit, the UK established an independent approval mechanism for genetically engineered (biotech) products but has lagged behind the EU in approving new events. As discussed in more detail in our latest [Agricultural Biotechnology Annual report](#), the ever-growing backlog includes multiple soybean and canola events. This is providing an increasing impediment to imports of these products, including from the United States.

This backlog of approvals compared to the EU could be resolved as a result of the Sanitary & Phytosanitary (SPS) agreement the UK is negotiating with the EU, which envisages food safety rules in Great Britain being aligned with EU regulations. The UK government has previously championed the potential opportunities arising from its Precision Breeding Act (2023) and the subsequent detailed regulations setting the framework to commercialize precision-bred plants. (Precision-bred plants are defined as plants whose genetic makeup has been altered through changes that could also have occurred naturally or through traditional breeding methods, without the introduction of exogenous genetic material.) Among the range of potential applications of this technology when it is authorized for use in England is pod-shattering resistance in rapeseed to reduce harvest losses. The UK government has stated its intention of seeking an exception for the Precision Breeding Act from the default of aligning with EU food safety rules. However, as negotiations between the UK and EU are ongoing, it is unclear whether any carve out (if successfully negotiated) will be permanent or just a stop-gap measure until the EU implements its own New Genomic Techniques regulation.

Agri-Environment Options

As noted in last year's Oilseeds and Products Annual report, the roll out of the post-Brexit farming incentive schemes is having an apparent impact on oilseeds production, albeit a complex and changeable one. In England, where the vast majority of the UK rapeseed crop is grown, increased payment rates offered for actions contained in the Sustainable Farming Incentive (SFI) scheme was cited as a factor in the historically low plantings in MY 2024/25 and 2025/26. In a bad year for the oilseed rape crop, SFI options could provide almost twice the returns by comparison, making them an attractive alternative break in arable rotations given the balance of risk and reward.

In March 2025, however, the Department for Environment, Food and Rural Affairs (Defra) announced abruptly that it would no longer accept new applications to the SFI scheme, as it had reached its funding limit for the current budget cycle. Intuitively, this development would be expected to have released land to return to crops like oilseed rape, but since agreements already in place still continued it meant it was only farmers who had intended to join SFI or those with expiring agreements that were most affected. A greater impact on future rapeseed plantings might therefore be expected in MY 2027/28, especially as Defra has reduced payment rates for some of the in-field actions that were outcompeting break crops like oilseed rape in terms of the margins that could reliably be earned. The amount of land that becomes available for the 2027 harvest year could further be expanded should farmers with expiring agreements in Defra's other agri-environment scheme, Countryside Stewardship Mid-Tier, be excluded from SFI due to a combination of inflexibilities in the IT application system and because the available budget is once again exhausted.

Industry Campaign

In the face of the reduction in the area of rapeseed grown in the UK, industry groups have launched a 'Reboot Campaign' to raise the profile of the sector. During the last year, the campaign has had particular success in disseminating advice on a suite of practical, agronomic strategies aimed at combatting the Cabbage Stem Flea Beetle pest, with coverage of the ten-point plan featured in the specialist farming press. The success of this agricultural extension outreach has played a significant part in improving grower sentiment in the oilseed rape crop and beginning to reverse the decline in the area planted.

Forest Risk Commodities Regime

Primary legislative powers were included in the Environment Act 2021 to prohibit large businesses from using commodities produced on illegally deforested land, with subsequent announcements indicating that both soy and palm oil would be within scope of these provisions. However, the secondary regulations required to make the rules operational are still pending, with the UK government seemingly waiting to learn the lessons of the EU's approach to its Deforestation Regulation. As noted earlier in this report, in the absence of a government approved framework for certifying products as deforestation free, a price premium has developed for North American origin soy in UK animal feed rations as a proxy for a verifiably low-risk supply.
